A Lecture
ON
THE TREATMENT OF DYSENTERY

Delivered before the Royal Society of Medicine on Dec 20th, 1915,

By Lieut-Colonel Sir RONALD ROSS, K C B, F R S,

RECENTLY CONSULTING PHYSICIAN ON TROPICAL DISEASES MEDITERRANEAN EXPEDITIONARY FORCE.

Mr President and Gentlemen,—My object in this lecture is not to detail my own experiences and opinions upon the very large subject of the treatment of dysentery, so much as to elicit the experiences and opinions of the many medical men who are at present treating cases in Britain, in order that we may be able to compare notes, and, if possible, to consolidate our methods in this important branch of practice Fortunately, for some centuries past Britain has remained almost entirely free from this serious disease, and probably entirely free from the amœbic form of it, except in regard to patients who have been infected elsewhere The result has been that medical men in England have not been able themselves to collect experiences, and now perhaps find themselves called upon to treat large numbers of cases suffering from a malady with which they are not familiar But we must remember that nothing in the whole range of clinical practice requires greater experience, skill, and judgment than the treatment of dysentery in all its stages In fact, this subject has been almost the principal preoccupation of physicians in Egypt, Greece, and Italy and other warm climates for thousands of years

Treatment of Dysentery in the Past

In classical times the treatment, of course empirical, consisted largely of the use of oils, essential oils, wine, and dieting, not to mention some of the curious remedies which our predecessors were apt to advocate In what may be called the first work on tropical medicine—namely, that curious book "The Cures of the Diseases in Forraine Attempts of the English Nation," 1598, and recently republished by the Clarendon Press, and attributed to one George Wateson, who apparently gave his manuscript to Richard Hakluyt, we find the following instructions —

> To cure Las Cameras or Cameras de Sangre, which is the Bloodie Flux With the more expedition that medicine is ministred to the diseased of Cameras de Sangre, Laxativenes or Bloodie Flux there is the more possibilitie it should prevaile And detracting it, the Pacients often die suddenly without feeling much griefe For speedie and assured remedie thereof, the Pacients bodie must bee clensed of the slimines engendered in the passages of the nutriments, before anie sustenance can remaine in his bodie And for that purpose give to purge him in the morning, halfe a pint of white Wine coold wherin ½ ounce of Rubarb hath been sodden being small cut, putting in some Suger Candie to sweeten it And Immediately after he hath so purged, keepe at his navell Rosemarie sodden in strong Vinegar, applied in the morning and evening verie hot untill it be staied giving him often Quinces brused and rowled in Marmelet like Pils which hee should swallowe whole, and none of the Fruits, or meates before recited nor any more white wine but red wine of any sort And if it be on Land the livers of Goates (especiallie) Sheepe, or Bullocks rosted not willingly permitting the Pacient to eate any other meate And if at Sea, Rice only sodden in water rather than any thing else usuall there, untill the infirmitie is perfectly asswaged

Sydenham used to employ venesection followed by purgation and laudanum administered in a cordial, his treatment being based upon his pathogenical hypothesis that dysentery "is a fever turned inwardly on the bowels" Early last century calomel was much employed Morehead in the middle of last century still supported the use of blood letting and calomel but added ipecacuanha, and, of course, used blisters and fomentations

Ipecacuanha

The most important event in the history of the treatment of dysentery was the employment of ipecacuanha which was first advocated in 1600 and then described by Piso and Marcgraf in 1648 Later in the same century the Dauphin, son of Louis XIV, was successfully treated by Helvetius with ipecacuanha, which he had obtained from Brazil, and Helvetius obtained a great reputation by the use of the drug, which he kept a secret, though he was ultimately prevailed upon to disclose the secret for a sum of a thousand louis d'or Since then the fortunes of ipecacuanha have varied from time to time just as did the fortunes of cinchona bark At times vaunted as specifics, and at times condemned as useless, probably both drugs suffered much from being given in quite inadequate doses and for periods which were too short to compass complete cure The use of large dosage seems to have been revived by Balmain at the beginning of last century, just as the use of large dosage of quinine was revived by Maillot some years later. Balmain prescribed up to two drachms of the powder, with 60 drops of laudanum, and claimed that one or two of these doses were often sufficient to establish complete cure I am not sufficient of a medical historian to know whether the credit was due to him or to Docker, but it is often maintained that the latter was the first really to claim the rank and title of specific for ipecacuanha in dysentery—which was something to have done, and for which he received a special pension by the Government of India.

Experience of Dysentery in India

In the year 1881, when I entered the Indian Medical Service and went to Netley, ipecacuanha was certainly in high favour, and I remember the fine lectures on the subject given by Surgeon General McLean No one more strongly emphasised the wonderful powers of ipecacuanha, not only in dysentery, but as a preventive of hepatic abscess, even after the pus had begun to form I believe that all of his hearers (young men at the time) followed out his teaching in India afterwards He insisted upon massive dosage in spite of the frequent vomiting caused by it, and, so far as I remember, gave the drug the last thing at night on an absolutely empty stomach (if possible) and on a previous dose of opium At any rate this may also be described as the usual Indian treatment up to the days of emetine I suppose that there are few medical men in Indian practice who do not every day of their lives have under treatment at least half a dozen cases of acute or chronic dysentery, so that our experience was certainly large

Personally, I am a convinced believer in the specific value of ipecacuanha When I was staff surgeon at Bangalore I saw many cases of severe dysentery in officers returning from Burma and the Mofussil and never dreamed of treating such without this drug I remember particularly one such officer who was, we all thought, dying when brought in The first dose of ipecacuanha powder was vomited, but the second was retained, and the patient's recovery began next morning and was complete We used to repeat the ipecacuanha at least once a day for about a week or more in spite of vomiting, but, of course, patients often became habituated even to large doses in three or four days Later on I used to prefer giving opium every night, and the dose of ipecacuanha in bolus with a single mouthful of milk at about 4 o'clock in the morning, if a nurse to give it was available, and the patient was not allowed anything either to eat or to drink until about 9 A M I thought that with this method one daily dose sufficed Later in the case we used to combine 5 or 10 grains of tannic acid with the ipecacuanha, especially in cases of "running dysentery", but I believe that practice was generally opposed to the use of astringents until the disease had first been mastered by ipecacuanha Of course, in those days we did not know whether the dysentery was amœbic or bacillary, and gave ipecacuanha in both, and up to the present I am not by any means convinced that ipecacuanha is of no benefit in bacillary dysentery The extraordinary specific effect which it has upon the mucous membrane of the stomach and colon especially suggests that it may at least be partially destructive to the vegetable parasites as well as to the animal ones

I do not think that we used bismuth much in those days, nor calomel, nor the sulphates of sodium and magnesium And many of us were certainly opposed to enemata, at least in very new cases, as we thought that they were likely to have an irritating effect similar to that often produced by catheterisation Here, I admit, opinion differed largely, and I remember many cases in which enemata certainly did not kill the patient, although in acute cases they undoubtedly cause much depression and considerable pain I also remember a few cases in which I thought that ipecacuanha had stopped the progress of commencing hepatic abscess—and also some, I fear, in which it failed to do so

In cases of chronic dysentery—cases whom we often found extremely difficult to treat, and indeed who have often become chronic simply because they refuse the treatment advised by their medical attendants—ipecacuanha was often given daily for some weeks, was then remitted for another week or so, and commenced again, and so on There were many retired officers in Bangalore suffering from this disease and from sprue, and the difficulty of the physicians almost always lay in dealing with the patient as much as in dealing with the disease, and everyone knows the state of irritability and impatience to which chronic dysentery and sprue reduce their victims In *chronic* dysentery enemata were, of course, much more certainly used than in acute dysentery, and nitrate of silver was almost a classical drug for the purpose We heard nothing in those days of appendicostomy, but dieting was a science in itself, requiring not only the greatest skill of the clinician but an obedience in the patient which was seldom met with

INTESTINAL AMŒBÆ

So far as I can ascertain it was chiefly the work of Kartulis in Alexandria which first definitely incriminated intestinal amœbæ as pathogenic organisms, partly in consequence of his admirable and long continued clinical studies partly by his discovery of amœbæ in the sterile pus of hepatic abscess, and partly by his experiments on kittens This work was commenced about 1880 and was already progressing when Koch visited Alexandria in 1883 The previous studies of Lewis and Cunningham had led these workers to think that these organisms were merely pseudoparasites in men, though they (or rather the latter) thought they were true parasites in cattle, and Celli and Fiocca and other workers seemed inclined to support them As the result of my own studies in Bangalore, both on amœbæ and on the intestinal flagellates which abounded there, I felt almost convinced that all these organisms are, or at least may be, injurious to the host—and still think so It appears to me to be a very rash statement to make that any parasite is quite innocuous One might as well say that a grain of dust in a watch is harmless, because it does not always stop the mechanism Certainly amœbæ may remain comparatively innocuous for considerable periods let us say in the pockets of small and few ulcers in the intestines, or even in its lumen, but we never know whether they *cannot at any moment produce* serious lesions or relapses of old lesions or may aggravate the lesions caused by other organisms And it still seems to me to be a safe teaching that we should consider all intestinal amœbæ and flagellates to be potentially dangerous However this may be, the role of certain amœbæ in dysentery has now been almost generally *accepted*

Captain (now Colonel) Patrick Hehir, C B , I M S and myself certainly recognised both amœbæ and flagellates in India in cases of dysentery and diarrhœa as early as 1896—see, for example, my paper in the *Indian Medical Service Gazette* for May, 1897, so that Sir Leonard Rogers is scarcely *justified* in claiming that he first *discovered amœbic dysentery in India in 1901 (p 17 of his* book), but *Sir Leonard Rogers can well afford to lose* this small distinction in comparison with the immense distinction which he has deservedly obtained for his elaboration of the treatment of dysentery by emetine

EMETINE

Emetine was first separated *from ipecacuanha by* Pelletier and Magendie in 1817 and was, I *believe*, first recommended *for dysentery by Bardsley* of Manchester in 1829, while Tull Walsh gave it *by* the mouth in 1891 But it was the elaborate studies of Rogers which first established the use of it (the hydrochloride) in 1912 and later so that it has *now been before* the profession for more than three years I believe that it is *accepted* everywhere, not perhaps as *being* essentially superior to ipecacuanha powder, but because the hypodermic injection of it is much less troublesome *to the* patient Personally, I think that the hypodermic use brings the drug more directly into conflict with the amœbæ at the bottom of the ulcers, while ipecacuanha does more to attack amœbæ on the *surface* of the mucous membrane and in the lumen of the intestines *so that* I am inclined to *favour* the use of both at the proper stages in the treatment But as an immediately applicable routine treatment the hypodermic *injection of* emetine hydrochloride has certainly become a great boon to humanity *for* which we owe a debt to Sir Leonard Rogers which cannot ever be repaid

I *must* however again mention the use of the sulphates of magnesium and sodium apparently originated *for* dysentery by the French physicians in the middle of last century and which use has now become almost universal in bacillary dysentery so that many think that we have specifics against both forms of the disease According to many, ipecacuanha and emetine are powerless against bacillary dysentery, while the saline purgatives are powerless against amœbic dysentery

DYSENTERY IN THE FORCES IN THE MEDITERRANEAN

I now come to the almost unique experience which we have recently had in connexion with cases of dysentery among soldiers As was to be expected, both forms of dysentery have occurred largely among the troops near the Mediterranean and the Red Sea Apparently bacillary dysentery prevailed up to midsummer, but after that there was certainly an epidemic of amœbic dysentery in July and August I was then on duty in Alexandria as consulting physician for tropical diseases, and had most unusual opportunities for studying the practice of the physicians in all the hospitals On Oct 17th we held a meeting at Alexandria, the Principal Director of the Medical Services being in the chair, to discuss the treatment of acute dysentery, and no less than 16 papers were read on that occasion Subsequently we held another meeting on the pathology of dysentery, which the able pathologists of the hospitals had been carefully considering, and I think that altogether we could claim to know something about the subject, at least as regards the forms of dysentery and diarrhœa, pure and simple, or complicating the typhoids which had been occurring up till then And I should now like to compare notes with officers who have all this time been practising in England on such of the cases as were invalided home

Certainly up to June amœbæ had not been easily found in Egypt, but towards the end of July they began to be recovered without difficulty in a large number of cases, and this state of things continued till the end of September or later After this, however, whether due to the large use of emetine in early cases or to the natural decay of the epidemic, amœbæ began to become more scarce, and I gathered from men who have worked long in Egypt that amœbic dysentery is likely to be supplanted by bacillary dysentery in the winter This, of course, is the almost general rule, for amœbic dysentery is especially a disease of hot climates, and one which tends to be always prevalent more in the summer than in the cool season, and more in low latitudes than in high ones Unfortunately, however, amœbic dysentery tends to be such a chronic complaint that the treatment of it continues to interest us long after the commencement of epidemics, and we have to guard not only against the chronic form of it but against the terrible hepatic abscesses which so frequently follow it

TREATMENT OF AMŒBIC DYSENTERY

As soon as we recognised the presence of amœbic dysentery among the troops emetine began to be employed by, I believe, every officer in charge of wards on the medical side, and, indeed, the Principal Director issued urgent orders to use it in every case of suspicious dysentery without waiting for a definite diagnosis as to the exact nature of the case In my opinion this order was absolutely demanded and proved to be very beneficial.

All those who have had experience of dysentery will, I think, agree with the first sentence which I have already quoted from that old writer, George Wateson, to the effect that the sooner that treatment is commenced in dysentery the more it is likely to prevail Once the amœbæ have begun their destructive trenching and mining under the mucosa there is apparently in many cases no natural limit to their activities, and they will soon end—as we unfortunately saw in necropsy after necropsy—by removing up to 90 per cent or more of the surface Every hour, therefore, counts at the beginning of the infection, and the delay of a few weeks often means almost irreparable ruin to the colon, even if the patient survives It appears to me to be useless to wait for laborious laboratory examinations as to the exact nature of the infection. Emetine is so benign a drug when given subcutaneously that it may well be administered on the chance that the infection is amœbic, just as it is the universal practice in the tropics to give quinine in nearly all tropical fevers without waiting for a pathological diagnosis—at least, if this is likely to be delayed for more than a few hours As in fever, so in dysentery we strike our preliminary blow on the chance that it will destroy an enemy whose presence we have reason only to suspect The results were remarkable Of course, owing to many difficulties the order referred to could not take full effect under several weeks, but after that I was informed by everyone that the newer cases were not of so grave a type as the earlier ones

I will now digress for a moment to emphasise a point which appears to me to be of great importance The large bulk of the troops came from Britain, Australia, and New Zealand, and were therefore men who had never had amœbic dysentery before Many of the cases were at first exceedingly grave—as grave, in fact, as I have ever seen among European troops freshly arrived in India Many of them had died before reaching the base hospitals, and those that survived had frequently reached the condition of "running dysentery," which always suggests to me that a large proportion of the mucosa is already destroyed. But, on the other hand, it was remarkable that among the Indian troops who are exposed to amœbic dysentery from childhood, there was not nearly the same frequency of severe cases I was, in fact, informed at the Indian Hospital that they did not suffer much from the disease, and that the cases which occurred were comparatively slight From this and other considerations I am therefore led to believe that in amoebic dysentery, as in malaria and many other diseases, there is likely to be a certain amount of immunity acquired during childhood in localities where such dysentery is endemic, and that, conversely, there is no such acquired immunity among the inhabitants of non endemic areas I think, then, that among the European and Australian troops we had to deal with acute amoebic dysentery in its most unmodified and malignant form This point must be remembered in connexion with the results of emetine treatment The studies of Rogers and of many Indian physicians were carried out mostly upon Indian patients —which probably explains the very rapid action of the drug, and we could hardly expect that we should have equally rapid results among the European troops in the Mediterranean

METHOD OF TREATMENT WITH EMETINE

Nevertheless, we were all convinced of its great, and indeed remarkable, efficacy As a general rule, doses of 1 grain of the hydrochloride a day were prescribed, either given in one subcutaneous injection or given in two doses morning and evening Practice differed considerably as to the number of doses administered In one hospital the rule was

was vomited, but the second was retained, and the patient's recovery began next morning and was complete We used to repeat the ipecacuanha at least once a day for about a week or more in spite of vomiting, but, of course, patients often became habituated even to large doses in three or four days Later on I used to prefer giving opium every night, and the dose of ipecacuanha in bolus with a single mouthful of milk at about 4 o'clock in the morning, if a nurse to give it was available, and the patient was not allowed anything either to eat or to drink until about 9 A.M I thought that with this method one daily dose sufficed Later in the case we used to combine 5 or 10 grains of tannic acid with the ipecacuanha, especially in cases of "running dysentery", but I believe that practice was generally opposed to the use of astringents until the disease had first been mastered by ipecacuanha Of course, in those days we did not know whether the dysentery was amœbic or bacillary, and gave ipecacuanha in both, and up to the present I am not by any means convinced that ipecacuanha is of no benefit in bacillary dysentery The extraordinary specific effect which it has upon the mucous membrane of the stomach and colon especially suggests that it may at least be partially destructive to the vegetable parasites as well as to the animal ones

I do not think that we used bismuth much in those days, nor calomel, nor the sulphates of sodium and magnesium And many of us were certainly opposed to enemata, at least in very new cases, as we thought that they were likely to have an irritating effect similar to that often produced by catheterisation Here, I admit, opinion differed largely, and I remember many cases in which enemata certainly did not kill the patient, although in acute cases they undoubtedly cause much depression and considerable pain I also remember a few cases in which I thought that ipecacuanha had stopped the progress of commencing hepatic abscess—and also some, I fear, in which it failed to do so

In cases of chronic dysentery—cases whom we often found extremely difficult to treat, and indeed who have often become chronic simply because they refuse the treatment advised by their medical attendants—ipecacuanha was often given daily for some weeks, was then remitted for another week or so, and commenced again, and so on There were many retired officers in Bangalore suffering from this disease and from sprue, and the difficulty of the physicians almost always lay in dealing with the patient as much as in dealing with the disease, and everyone knows the state of irritability and impatience to which chronic dysentery and sprue reduce their victims In chronic dysentery enemata were, of course, much more certainly used than in acute dysentery, and nitrate of silver was almost a classical drug for the purpose We heard nothing in those days of appendicostomy, but dieting was a science in itself, requiring not only the greatest skill of the clinician but an obedience in the patient which was seldom met with

INTESTINAL AMŒBÆ

So far as I can ascertain it was chiefly the work of Kartulis in Alexandria which first definitely incriminated intestinal amœbæ as pathogenic organisms, partly in consequence of his admirable and long continued clinical studies, partly by his discovery of amœbæ in the sterile pus of hepatic abscess, and partly by his experiments on kittens This work was commenced about 1880 and was already progressing when Koch visited Alexandria in 1883 The previous studies of Lewis and Cunningham had led these workers to think that these organisms were merely pseudoparasites in men, though they (or rather the latter) thought they were true parasites in cattle, and Celli and Fiocca and other workers seemed inclined to support them As the result of my own studies in Bangalore, both on amœbæ and on the intestinal flagellates which abounded there, I felt almost convinced that all these organisms are, or at least may be, injurious to the host—and still think so It appears to me to be a very rash statement to make that any parasite is quite innocuous One might as well say that a grain of dust in a watch is harmless, because it does not always stop the mechanism Certainly amœbæ may remain comparatively innocuous for considerable periods, let us say in the pockets of small and few ulcers in the intestines or even in its lumen, but we never know whether they cannot at any moment produce serious lesions or relapses of old lesions or may aggravate the lesions caused by other organisms And it still seems to me to be a safe teaching that we should consider all intestinal amœbæ and flagellates to be potentially dangerous However this may be, the rôle of certain amœbæ in dysentery has now been almost generally accepted

Captain (now Colonel) Patrick Hehir, C B, I M S, and myself certainly recognised both amœbæ and flagellates in India in cases of dysentery and diarrhœa as early as 1896—see, for example, my paper in the *Indian Medical Service Gazette* for May, 1897, so that Sir Leonard Rogers is scarcely justified in claiming that he first discovered amœbic dysentery in India in 1901 (p 17 of his book), but Sir Leonard Rogers can well afford to lose this small distinction in comparison with the immense distinction which he has deservedly obtained for his elaboration of the treatment of dysentery by emetine

EMETINE

Emetine was first separated from ipecacuanha by Pelletier and Magendie in 1817 and was, I believe, first recommended for dysentery by Bardsley of Manchester in 1829, while Tull Walsh gave it by the mouth in 1891 But it was the elaborate studies of Rogers which first established the use of it (the hydrochloride) in 1912 and later, so that it has now been before the profession for more than three years I believe that it is accepted everywhere, not perhaps as being essentially superior to ipecacuanha powder, but because the hypodermic injection of it is much less troublesome to the patient Personally, I think that the hypodermic use brings the drug more directly into conflict with the amœbæ at the bottom of the ulcers, while ipecacuanha does more to attack amœbæ on the surface of the mucous membrane and in the lumen of the intestines, so that I am inclined to favour the use of both at the proper stages in the treatment But as an immediately applicable routine treatment the hypodermic injection of emetine hydrochloride has certainly become a great boon to humanity for which we owe a debt to Sir Leonard Rogers which cannot ever be repaid

I now come to the almost unique experience which we have recently had in connexion with cases of dysentery among soldiers As was to be expected, both forms of dysentery have occurred largely among the troops near the Mediterranean and the Red Sea Apparently bacillary dysentery prevailed up to midsummer, but after that there was certainly an epidemic of amœbic dysentery in July and August I was then on duty in Alexandria as consulting physician for tropical diseases, and had most unusual opportunities for studying the practice of the physicians in all the hospitals On Oct 17th we held a meeting at Alexandria, the Principal Director of the Medical Services being in the chair, to discuss the treatment of acute dysentery, and no less than 16 papers were read on that occasion. Subsequently we held another meeting on the pathology of dysentery, which the able pathologists of the hospitals had been carefully considering, and I think that altogether we could claim to know something about the subject, at least as regards the forms of dysentery and diarrhœa, pure and simple, or complicating the typhoids which had been occurring up till then And I should now like to compare notes with officers who have all this time been practising in England on such of the cases as were invalided home.

Certainly up to June amœbæ had not been easily found in Egypt, but towards the end of July they began to be recovered without difficulty in a large number of cases, and this state of things continued till the end of September or later After this, however, whether due to the large use of emetine in early cases or to the natural decay of the epidemic, amœbæ began to become more scarce, and I gathered from men who have worked long in Egypt that amœbic dysentery is likely to be supplanted by bacillary dysentery in the winter This, of course, is the almost general rule, for amœbic dysentery is especially a disease of hot climates, and one which tends to be always prevalent more in the summer than in the cool season, and more in low latitudes than in high ones Unfortunately, however, amœbic dysentery tends to be such a chronic complaint that the treatment of it continues to interest us long after the commencement of epidemics, and we have to guard not only against the chronic form of it but against the terrible hepatic abscesses which so frequently follow it

TREATMENT OF AMŒBIC DYSENTERY

As soon as we recognised the presence of amœbic dysentery among the troops emetine began to be employed by, I believe, every officer in charge of wards on the medical side, and, indeed, the Principal Director issued urgent orders to use it in every case of suspicious dysentery without waiting for a definite diagnosis as to the exact nature of the case In my opinion this order was absolutely demanded and proved to be very beneficial.

All those who have had experience of dysentery will, I think, agree with the first sentence which I have already quoted from that old writer, George Watson, to the effect that the sooner that treatment is commenced in dysentery the more it is likely to prevail Once the amœbæ have begun their destructive trenching and mining under the mucosa there is apparently in many cases no natural limit to their activities, and they will soon end—as we unfortunately saw in necropsy after necropsy—by removing up to 90 per cent or more of the surface Every hour, therefore, counts at the beginning of the infection, and the delay of a few weeks often means almost irreparable ruin to the colon, even if the patient survives It appears to me to be useless to wait for laborious laboratory examinations as to the exact nature of the infection Emetine is so benign a drug when given subcutaneously that it may well be administered on the chance that the infection is amœbic, just as it is the universal practice in the tropics to give quinine in nearly all tropical fevers without waiting for a pathological diagnosis—at least, if this is likely to be delayed for more than a few hours As in fever, so in dysentery we strike our preliminary blow on the chance that it will destroy an enemy whose presence we have reason only to suspect The results were remarkable Of course, owing to many difficulties the order referred to could not take full effect under several weeks, but after that I was informed by everyone that the newer cases were not of so grave a type as the earlier ones

I will now digress for a moment to emphasise a point which appears to me to be of great importance The large bulk of the troops came from Britain, Australia, and New Zealand, and were therefore men who had never had amœbic dysentery before Many of the cases were at first exceedingly grave—as grave, in fact, as I have ever seen among European troops freshly arrived in India. Many of them had died before reaching the base hospitals, and those that survived had frequently reached the condition of "running dysentery," which always suggests to me that a large proportion of the mucosa is already destroyed. But, on the other hand, it was remarkable that among the Indian troops, who are exposed to amœbic dysentery from childhood, there was not nearly the same frequency of severe cases I was, in fact, informed at the Indian Hospital that they did not suffer much from the disease, and that the cases which occurred were comparatively slight From this and other considerations I am therefore led to believe that in amoebic dysentery, as in malaria and many other diseases, there is likely to be a certain amount of immunity acquired during childhood in localities where such dysentery is endemic, and that, conversely, there is no such acquired immunity among the inhabitants of non endemic areas I think, then, that among the European and Australian troops we had to deal with acute amoebic dysentery in its most unmodified and malignant form This point must be remembered in connexion with the results of emetine treatment The studies of Rogers and of many Indian physicians were carried out mostly upon Indian patients —which probably explains the very rapid action of the drug, and we could hardly expect that we should have equally rapid results among the European troops in the Mediterranean

METHOD OF TREATMENT WITH EMETINE

Nevertheless, we were all convinced of its great, and indeed remarkable, efficacy As a general rule, doses of 1 grain of the hydrochloride a day were prescribed either given in one subcutaneous injection or given in two doses morning and evening Practice differed considerably as to the number of doses administered In one hospital the rule was that of three days on and three days off, and in another hospital the rule was five days on and five days off, while many practitioners preferred to give it daily, even for some weeks, without intermission Indeed, the practice in India has frequently been to administer it, not only for weeks, but for many months, and I have heard of cases who have altogether had a hundred doses or more But opinion began soon to be divided upon this point in rather an abrupt manner In one hospital three cases of dysentery died without our being able to find any very obvious cause of death, and some suspicion was aroused that the death may have been due to heart failure owing to cumulative action of the emetine

These cases were admirably reported by the medical officers in charge, but on considering them carefully I doubted much whether the fatal result could in any way be attributed to the drug Two of the cases died, indeed, about a week after the last dose of emetine, and both these cases had mysterious rises of temperature for some days before death, these suggesting that death was really caused by some secondary infection which could not be traced clearly at the necropsy The third case died four days after the last dose of emetine, though he was convalescent and had been allowed out of bed Even in this instance the case against emetine was extremely weak, because the total amount of emetine which the patient had received from the beginning scarcely amounted to what Rogers calculated is a single lethal dose—namely, about 15 grains for a man There was fatty degeneration of the heart in all these cases, but no more than is frequently found after any grave illness

On the other hand, numerous patients had received emetine for more than 30 days without exhibiting any bad effects which could at all be traced to the drug, and Indian officers especially were not inclined to admit that emetine is at all cumulative or mischievous in its results Nevertheless, practice gradually crystallised into the formula that, unless there was very strong reason for continuing emetine, it should be remitted, at least for a time after about ten days, especially if it had ceased to do good And, on the whole, I think that this is the best practice in acute dysentery[1]

COMPLEX INFECTIONS

As was to be expected, about 10 or 20 per cent of the cases failed to be cured by emetine I do not mean that all of these patients died, but that the dysentery gradually merged into the chronic form Most, but not all, of these cases were patients who had not received emetine early in the infection, and in whom therefore the mucosa was probably destroyed over a large surface before the treatment was commenced And this introduces a very important factor in treatment

Emetine can only destroy the parasites in the ulcers, it cannot heal the lesions themselves Now it is almost or quite certain that in most cases the original trench work of the amœbæ is followed by an extensive bacillary invasion of some kind At our pathological meeting in Alexandria, difference of opinion was expressed as to whether these secondary organisms were always *Bacillus dysenteriæ* of any strain, or others, including the normal flora of the intestine, and prolonged researches will be required before this point is settled We must, of course, understand (though I have not stated it clearly up to now) that complex infections were exceedingly common. For obvious reasons it is quite impossible for me to give figures, but I gathered from continual visits to the hospitals that this was the case Thus, both the amœbic and the bacillary forms of dysentery occurred together in a certain proportion of cases, and in others both forms complicated the typhoids, or were complicated by obstinate diarrhœas—many of the latter being probably due to the flagellates

Now in all such cases we could hardly expect emetine to do more than its own proper work, it destroyed the amœbæ, but the patient was then obliged to deal with the secondary or complicating maladies The text book picture of simple amœbic dysentery was therefore not the only one seen It frequently happened that cases which were brought in for the typhoids showed dysentery in convalescence, and even died from it We were at first inclined to attribute these cases to hospital infections but later came to the conclusion that the dysentery infection had probably been present from the beginning

I became very convinced of this from the remarkable results of Lieutenant G B Bartlett, R A M C (T), pathologist to one of the hospitals He found dysenteric lesions in 33 necropsies, and has kindly given me a preliminary classification of these, pending further studies which he will, I hope, publish in detail Out of the 33 cases 15 died from exhaustion, 2 from typical tropical abscess of the liver, 2 from perforation of the dysenteric ulcers, 2 from hæmorrhage, 2 from typhoid or paratyphoid, and no fewer than 10 from other causes such as wounds, empyema, septicæmia cirrhosis of the liver, &c Now it is remarkable that in many of these cases dysentery had not been diagnosed at all during life although post mortem the dysenteric lesions were found sometimes to be extensive and severe Out of these 33 cases, moreover, 16 were found to be purely amœbic 3 were amœbic with typhoid ulceration and in 14 there was evidence in the intestine (or rarely in lymph glands, spleen, liver, or kidneys) of a secondary infection on the top of the amœbic ulceration

We are thus forced to infer that the amœbic ulceration may not always declare itself during life in the form of a typical dysentery which can be diagnosed by the well known signs In fact I personally think that much mischief may be caused by the amœbæ without any signs whatever and that in many cases the typical disease does not begin to show itself until some secondary intestinal invasion has taken place on the top of the trench work of the amœbæ How long this larval form of amœbic dysentery can continue I cannot say, but in many cases it had continued through the whole course of an intercurrent typhoid infection Indeed I was much inclined to recommend on the strength of Dr Bartlett s figures and of other observations that emetine should be given to all hospital patients as a preventive just as we give quinine to almost all hospital patients in a very malarious locality But the recommendation was hardly necessary, since most officers in charge of wards early became very much alive to this danger, and were giving the emetine very generally in consequence

---

[1] Since this was written an important preliminary note has been published in the *British Medical Journal* of Dec 16th by Dr H H Dale F.R.S., stating that experiments on cats and rabbits showed that hypodermic injections of emetine hydrochloride continued from three to ten days in doses above those usually administered in cases of dysentery caused diarrhœa emaciation and other symptoms with fatal results Dr Dale thinks that these experiments suggest that "emetine can produce cumulative poisoning of serious importance" I presume that he means rather that the effect is cumulative than that the drug itself is cumulative—another thing If one dose can cause intestinal hyperæmia I presume that too many and too large doses can exaggerate this effect without the drug itself being actually cumulative We await further experiments, but the few already made fully justify the note of caution sounded by those to whom I have just referred

While I was in Alexandria pure bacillary dysentery was not very common, though we saw a fair number of cases There were also, of course, a proportion of cases which did not certainly belong to either group, and we had the usual difficulties in the way of diagnosis The pathologists scarcely had time at first to make very minute studies, and everyone knows that amœbæ may be easily overlooked unless plenty of time is given to the search I will not say more under this head, as a central laboratory has now been established and will deal much more thoroughly with such questions in the future

Returning then to treatment, our cases practically divided themselves into two groups—those in which about one week's emetine treatment practically resolved the dysentery, and those in which it failed to do so Of course, the latter cases were by far the more troublesome, and they generally resulted in what I have always known as running or even incontinent dysentery I fear that some of our best clinicians admitted their failure in dealing with these, which, however form only a small percentage of the cases Post mortem they always showed most extensive lesions, and, indeed, an almost entire destruction of the mucosa Many of the cases died, but, as I have already said, others resulted in chronic dysentery and were invalided, and are now probably under treatment in this country

PURGATIVE ACTION OF SULPHATES

Now, regarding the sulphates of sodium and magnesium, these have long been recognised as invaluable for the treatment of bacillary dysentery Their purgative action is not due to peristalsis, but to the increase of the secretion of fluid and at the same time to the retardation of its absorption According to the researches of Hay the dose produces increased secretion of fluid as it passes downwards, and the salts do not purge when given intravenously But the more recent experiments of Cook and Schlesinger suggest that the drugs are first absorbed from the stomach and then cause a rush of fluid from the mucosa of the large intestine, and these results certainly accord more with the fact, often seen, that the salts purge within half an hour after administration It was also shown that bismuth meals administered at the same time as the sulphates succeeded in travelling downwards a very little distance before the fluid began to collect in the large intestine, which proves the same thing

These points are of great importance in connexion with the treatment in dysentery I infer that the salts act in this disease simply by flushing out the large intestine and washing away the parasites, amœbic or bacillary, by a strong current from *within*—that is, from the blood itself In fact, they probably produce the same, or better, effects than would be produced by energetic washing of the surface from without That is to say, as long as these salts continue to be given the dysenteric producing organism cannot easily get a footing within the mucosa Of course, this reasoning is hypothetical but, taken in connexion with the proved efficacy of the drug it encourages us to use them in both forms of dysentery Indeed, the practice of administering the sulphates together with emetine in the earliest days of a dysentery is now becoming almost universal, the emetine kills any amœbæ that may be present, and the salts wash them and injurious bacteria out of the follicles In further advanced cases—say those of several weeks' duration—the use of the salts becomes more problematical in the case of amœbic dysentery, and one must be on guard against exhausting patients who have been extremely purged by the disease itself, especially if this has already taken the form of running dysentery On the other hand, I admit that many practitioners gave the salts in almost all cases of whatever duration

MEDICINAL TREATMENT

The treatment of running acute dysentery is the great problem in most cases, and, I regret to say, one which cannot always be solved, as admitted by some of the most experienced practitioners in all countries Here the mischief has been already accomplished, and we are probably in the presence of an almost denuded colon. We tried antidysenteric sera in many such cases on the mere chance that they might destroy the specific bacteria if present, there being generally not sufficient time to make minute pathological studies And the treatment was said by many to be remarkably beneficial in a certain proportion of cases But others were not so favourably inclined to it, and others again argued that an ordinary horse serum would probably have been just as useful I have suggested that polyvalent sera might be put on the market against other intestinal flora than the specific ones, and hope that such will be tried before long

Failing sera, we had recourse to medicinal treatments I always urged the bismuth treatment elaborated by Deeks in Panama and consisting of a heaped teaspoonful of the subnitrate three or four times a day The utility of this medication is supposed to depend not only upon the astringent value of bismuth, but also upon a chemical change, and lastly upon the mechanical action of the powder, which is likely to injure amœbæ by attrition At all events, bismuth in these and smaller doses is very generally given in dysentery, was largely employed throughout the hospitals in Alexandria, and certainly I think, proved distinctly useful It was generally administered continuously, beginning a day or two after the initial treatment with emetine was commenced

I have always liked tannic acid in conjunction, say up to 10 grains for each dose In fact, tannic acid has been used for a long time, and was often administered together with ipecacuanha powder, because it tends to check the vomiting induced by the latter, as well as because of its astringent effect But it is a good general rule *not to use any* astringents at all too early—*that* is, *until the* specific remedies have had time to take effect After that happens, however, opium, bismuth, tannic acid, catechu, *and other astringents* do often succeed in terminating *the attack* very rapidly I regret to say, however, that many cases became cases of established running dysentery in spite of all treatment

Collapse is another very difficult condition to deal with Lieutenant Colonel A H Lister, of one of the hospitals in Alexandria, often used the subcutaneous infusion *of hypertonic* salines together that of three days on and three days off, and in another hospital the rule was five days on and five days off, while many practitioners preferred to give it daily, even for some weeks, without intermission Indeed, the practice in India has frequently been to administer it, not only for weeks, but for many months, and I have heard of cases who have altogether had a hundred doses or more But opinion began soon to be divided upon this point in rather an abrupt manner In one hospital three cases of dysentery died without our being able to find any very obvious cause of death, and some suspicion was aroused that the death may have been due to heart failure owing to cumulative action of the emetine

These cases were admirably reported by the medical officers in charge, but on considering them carefully I doubted much whether the fatal result could in any way be attributed to the drug Two of the cases died, indeed, about a week after the last dose of emetine, and both these cases had mysterious rises of temperature for some days before death, these suggesting that death was really caused by some secondary infection which could not be traced clearly at the necropsy The third case died four days after the last dose of emetine, though he was convalescent and had been allowed out of bed Even in this instance the case against emetine was extremely weak, because the total amount of emetine which the patient had received from the beginning scarcely amounted to what Rogers calculated is a single lethal dose—namely, about 15 grains for a man There was fatty degeneration of the heart in all these cases, but no more than is frequently found after any grave illness

Collapse is another very difficult
deal with Lieutenant Colonel A H
of the hospitals in Alexandria, often
cutaneous infusion of hypertonic salines

with 10 minims of adrenalin solution, 1 in 1,000 every four hours, injected hypodermically, with very good results, and strongly recommends the adrenalin

Opium is, of course, an invaluable drug throughout the treatment, and, though some practitioners appear to be nervous about it, I think that the use of it is really general at all stages

ENEMATA —APPENDICOSTOMY

We now come to a very vexed question—namely, the use of enemata in acute dysentery There is no question of their use in chronic dysentery, especially of low down ulceration, but some of us felt that they are contra indicated in very early cases The disease is itself complicated with purging, and if the sulphates are being given at the same time, there is a continual washing out of the bowel from within In such cases I really cannot understand the rationale of using massive lavations, which depress the patient and may even rupture the very thin walls of the ulcers, and we never know how old and thin the ulcers may be Others object to them on the ground that they may engender secondary infections from without, and I have a feeling that the use of enemata is somewhat too frequently followed by running dysentery Others again adopt enemata as a standard treatment

Such a great authority as Professor Kartulis is confident that tannic acid is most beneficial from the first Rogers often recommends quinine lavations Colonel Lister was an advocate of three or four ounces of warm olive oil containing a drachm
of ichthyol, preceded by a his suppository half
an hour before the injecti er has
always been employed in and I

several hours, and these baths can be repeated several times a day if the patient is not in too weak a condition. We could not try such baths much in Alexandria, but I would suggest them for use in the cases in this country Personally also I have always been much in favour of oils by the mouth Olive oil is an old remedy for dysentery in Italy A dessertspoonful of it with a pinch of salt may be given several times a day, but the patient soon sickens of it, and then I suggest the non purgative medicinal paraffins—which, indeed, may be given from the first I have often used these, and have observed that they appear in a saponified form in the stools—a form which is likely to be very injurious to all kinds of organisms and in fact, to smother them Indeed, this effect of oils is, I believe, well recognised

Innumerable drugs have been supposed to be curative of dysentery Kartulis told me that he had had very good results from a drug called Uzara (difficult to obtain in this country), and Dr Fingland recommended in THE LANCET of August 15th 1903 (p 456), the use of *Aplopappus baylahuen* (Parke, Davis, and Co) on the results obtained from three cases only The evidence on all such drugs is generally very weak, and they are scarcely to be tried unless all other measures have failed In this paper I have confined myself to the broader lines of treatment used by the majority of clinicians

DIET

Regarding diet in acute dysentery, I must say that after comparing the very various diets given by many medical men I am beginning to be almost sceptical as to whether any particular form presents any real advantage I have seen cases both improve and die with liquid diet, bland diets, and ordinary diets, and, in fact, cases which are not given the great advantages of perfected hospital dietaries are often those which suffer the least.

We are too apt to think that the form in which
fo esented to the stomach is also the form in
pears in the colon For example, bread
t for the stomach, but almost a liquid
colon, and the converse holds very
milk To be frank, I scarcely dare
this subject owing to the strong but
opinions held by medical men On
however, I am pretty convinced—
large bulks of fluid diet are injurious
g dysenteries It seems to me that
fluid are rapidly absorbed from the
rease the blood pressure, with the
d rushes out again from the ulcerated
intestine Whatever the explanation
observe that such large bulks of
ed sometimes within ten minutes by
ons which by no means benefit the
case is much the same as that of
fluid in the treatment of catarrhs
I prefer a comparatively dry but
running dysenteries
medical men would be almost
ypothesis, and would never dream
patient with anything but whey
on. Certainly in typhoid a
solid diet notoriously sends
, but the large intestine is
the stomach, and I have not
a similar effect in dysentery
officer told me that when he
presence of dysenteric

HEPATIC ABSCESS

I now come to the most important point of all—the prevention of hepatic abscess And this especially is the leading proposition before us here in England. Some months ago we in Alexandria heard from several sources that you in England had discovered only bacillary dysentery, and still, by many accounts amœbæ are not frequently found here This divergence of experiences can be explained in several ways, either on the hypothesis that the amœbæ have become scarce during the lapse of time, or that they have been destroyed in the majority of the cases by emetine, or that the epidemic of amœbic dysentery lasted only for a very short time Possibly also amœbæ were not found because they were not searched for frequently enough in each case By no means always do we discover the amœbæ in the first sample I remember an acute case in which I discovered them only on the fourth trial, though the previous trials had been very carefully conducted, and it stands to reason that we cannot give negative diagnoses on the strength of such extremely small samples as we usually examine On the whole, I think that in view of Lieutenant Bartlett's post mortem figures there was a vast amount of amœbic dysentery in the Mediterranean, even among persons in whom the disease was never diagnosed,

Now we must remember that hepatic abscess follows in a large proportion of amœbic infections, whether these infections have produced dysenteric symptoms or not On taking the histories of cases of hepatic abscess, we find no history of previous dysentery in something like a quarter of the cases —the probable truth being that the amœbic infection of the liver takes place from small intestinal pockets in which amœbæ had remained without causing widespread dysenteric lesions In fact, I have often thought that abscess follows the milder cases of dysentery more frequently than the severe ones Again, from some figures quoted by Rogers in the *Indian Medical Gazette* for November, 1912, we learn that the British army in India during the decade 1901–10 had one case of liver abscess for every seven cases of dysentery, more than 14 per cent If a similar proportion will be found to hold for Mediterranean dysentery, we can expect a very large number of cases of abscess

Prophylactic Treatment

We must remember that the abscesses do not appear only a few months *after* attacks of dysentery, but continue to appear for years afterwards Now this seems to me a very grave danger, and I would strongly urge that the only way to avoid it is to give courses of emetine or ipecacuanha in convalescent cases every month or so I would suggest emetine in grain doses for three days every month until the patient is finally returned to duty, and think that this should be administered whether any symptoms of dysentery remain or not As long as any amœbæ still live in the intestine, so long will the danger of abscess be present, or at least that is the safest hypothesis to live with And I do not care whether a positive diagnosis of amœbic dysentery has ever been made or not made If I myself had been attacked with dysentery I would certainly submit myself to this discipline without fail Acute dysentery is a grievous malady, but it is only the first act of the tragedy Chronic dysentery is the second act, and is still worse, but hepatic abscess is the third act and is worst of all We are too apt to look upon amœbic dysentery as being only a temporary affair easily cured by a few doses of the specific

Some clinicians (such as Colonel Robinson in Alexandria) think that ipecacuanha is still useful in the later stages of dysentery, and especially as a prophylactic, and I am inclined to agree with them Emetine destroys the parasites in the mucosa, but I doubt whether it can really have the same effect upon those which are living and perhaps abounding in the lumen For these perhaps the powder is still useful, and, I think, can be administered in much smaller doses after emetine has been given than would be useful without emetine For example, 5 grains each of ipecacuanha powder, Dover's powder, tannic acid, and sulphate of quinine can be administered the last thing at night on an empty stomach, without prefatory opium, and if given properly will not cause vomiting, at least after the first dose or two But this is a matter of personal opinion, and I think that as long as ipecacuanha is given in some form, the same result will be achieved Of course, if abscess is beginning to manifest itself in any way, return to full doses of emetine should be enjoined, combined, of course, with suitable diet Most people urge the entire absence of alcohol, but three of the worst cases of abscess ever seen by me in India occurred in teetotalers, and abscess is fairly frequent among Indians who never touch alcohol.

CONCLUSION

I have now kept you long enough, although I have practically dealt only, and that cursorily, with the treatment of acute dysentery Fortunately, I think, we are not yet in the presence of much of the chronic dysentery which will probably remain over from the epidemic The treatment of chronic dysentery is itself a very large subject requiring special consideration, and we can hardly deal with it now

Two points must be mentioned before I close The first is, that we thought of a method of diagnosing dysenteric ulceration by means of the X rays, and this method was ably worked out by Lieutenant Glasson, of one of the Alexandrian hospitals, whose paper will shortly appear in the Proceedings of this society Secondly, I should like to call attention to the excellent "Notes on the Treatment of Diarrhœa and Dysentery,"[2] recently written by Lieutenant Colonel Andrew Balfour, C M G, which will be useful to all concerned

In conclusion, I hope that we may now hear their views on the treatment of dysentery from some of the many medical officers who are now treating cases in England

---

[2] John Bale Sons and Danielsson.

BRIGHTON AND TUBERCULOUS PATIENTS —Since the taking over of the Brighton Poor law institution by the medical authorities certain Poor law tuberculous patients have been under treatment at the borough sanatorium, the agreed charge for which was 21s per week The Local Government Board meanwhile have intimated that they consider it desirable that the schemes for the institutional treatment of tuberculosis should make provision for all classes of the community, and if the corporation decided to treat tuberculous persons who are chargeable to the parish on the same terms as other non insured persons the corporation would receive a grant of one half the cost and the rates would, to that extent be relieved The guardians agreed to this arrangement and the corporation health committee recommended that it be adopted, effecting as it would as between the corporation and the guardians a net saving of £500 per annum The corporation at its meeting on Dec 16th last ratified the scheme with 10 minims of adrenalin solution, 1 in 1,000 every four hours, injected hypodermically, with very good results, and strongly recommends the adrenalin

Opium is, of course, an invaluable drug throughout the treatment, and, though some practitioners appear to be nervous about it, I think that the use of it is really general at all stages

ENEMATA —APPENDICOSTOMY

We now come to a very vexed question—namely, the use of enemata in acute dysentery There is no question of their use in chronic dysentery, especially of low down ulceration, but some of us felt that they are contra indicated in very early cases The disease is itself complicated with purging, and if the sulphates are being given at the same time, there is a continual washing out of the bowel from within In such cases I really cannot understand the rationale of using massive lavations, which depress the patient and may even rupture the very thin walls of the ulcers, and we never know how old and thin the ulcers may be Others object to them on the ground that they may engender secondary infections from without, and I have a feeling that the use of enemata is somewhat too frequently followed by running dysentery Others again adopt enemata as a standard treatment

Such a great authority as Professor Kartulis is confident that tannic acid is most beneficial from the first Rogers often recommends quinine lavations Colonel Lister was an advocate of three or four ounces of warm olive oil containing a drachm of ichthyol, preceded by a morphia suppository half an hour before the injection Nitrate of silver has always been employed in chronic dysentery, and I know many cases where it has certainly effected a cure, but nowadays we should use protargol or similar salts—and these were employed with fairly good results in many of our fresh cases If lavations are employed at all, I like warm water without salts, as it swells up and destroys the amœbæ, or warm and weak permanganate solution or warm and weak solution of quinine But I still do not favour this form of medication very much in acute dysentery

I was able to follow up only one case of acute dysentery in which appendicostomy was tried, and cannot say that the result was very brilliant There does not appear to me to be much *a priori* argument in favour of it The bowel can be washed out from within by means of the sulphates, and I am by no means convinced that external washing gives as much benefit in the case of the large intestine as it would do in the case of a superficial ulceration of the skin, while the operation itself and the wound made by it add a severe trial to patients who are already sorely tried by their malady At our discussion on dysentery Colonel Tubby expressed himself as opposed to appendicostomy for acute dysentery and even for chronic amœbic dysentery, but was less opposed to it for bacillary dysentery Irrigation with oil through the appendix appears to me to be more promising than that with other fluids and it was tried, but with doubtful results, in the case which I watched

SUBSIDIARY ITEMS OF TREATMENT

Regarding subsidiary items of treatment, I need scarcely insist upon the general use of cholera belts or warm applications to the abdomen In India I frequently used very hot hip baths, which I am certain give great relief, often lasting for several hours, and these baths can be repeated several times a day if the patient is not in too weak a condition We could not try such baths much in Alexandria, but I would suggest them for use in the cases in this country Personally also I have always been much in favour of oils by the mouth Olive oil is an old remedy for dysentery in Italy A dessertspoonful of it with a pinch of salt may be given several times a day, but the patient soon sickens of it, and then I suggest the non purgative medicinal paraffins—which, indeed may be given from the first I have often used these, and have observed that they appear in a saponified form in the stools—a form which is likely to be very injurious to all kinds of organisms and in fact, to smother them Indeed, this effect of oils is, I believe, well recognised

Innumerable drugs have been supposed to be curative of dysentery Kartulis told me that he had had very good results from a drug called Uzara (difficult to obtain in this country), and Dr Fingland recommended in THE LANCET of August 15th, 1903 (p 456), the use of *Aplopappus baylahuen* (Parke, Davis, and Co) on the results obtained from three cases only The evidence on all such drugs is generally very weak, and they are scarcely to be tried unless all other measures have failed In this paper I have confined myself to the broader lines of treatment used by the majority of clinicians

DIET

Regarding diet in acute dysentery, I must say that after comparing the very various diets given by many medical men I am beginning to be almost sceptical as to whether any particular form presents any real advantage I have seen cases both improve and die with liquid diet, bland diets, and ordinary diets, and, in fact, cases which are not given the great advantages of perfected hospital dietaries are often those which suffer the least.

We are too apt to think that the form in which food is presented to the stomach is also the form in which it appears in the colon For example, bread is a solid diet for the stomach, but almost a liquid one for the colon, and the converse holds very often with milk To be frank, I scarcely dare speak upon this subject owing to the strong but very opposite opinions held by medical men On one thing, however, I am pretty convinced—namely, that large bulks of fluid diet are injurious in very running dysenteries It seems to me that such bulks of fluid are rapidly absorbed from the stomach and increase the blood pressure, with the result that fluid rushes out again from the ulcerated surfaces of the intestine Whatever the explanation may be, we can observe that such large bulks of fluid are followed sometimes within ten minutes by copious evacuations which by no means benefit the patients The case is much the same as that of large bulks of fluid in the treatment of catarrhs and personally I prefer a comparatively dry but varied dietary in running dysenteries

Perhaps many medical men would be almost appalled by this hypothesis, and would never dream of presenting the patient with anything but whey, milk, broth and so on Certainly in typhoid a premature return to solid diet notoriously sends up the temperature, but the large intestine is farther away from the stomach, and I have not seen much evidence of a similar effect in dysentery At the same time, one officer told me that when he wished to diagnose the presence of dysenteric ulceration in a convalescent case of enteric he gave a meal of oatmeal porridge

HEPATIC ABSCESS

I now come to the most important point of all—the prevention of hepatic abscess And this especially is the leading proposition before us here in England Some months ago we in Alexandria heard from several sources that you in England had discovered only bacillary dysentery, and still, by many accounts amœbæ are not frequently found here This divergence of experiences can be explained in several ways, either on the hypothesis that the amœbæ have become scarce during the lapse of time, or that they have been destroyed in the majority of the cases by emetine, or that the epidemic of amœbic dysentery lasted only for a very short time Possibly also amœbæ were not found because they were not searched for frequently enough in each case By no means always do we discover the amœbæ in the first sample I remember an acute case in which I discovered them only on the fourth trial, though the previous trials had been very carefully conducted, and it stands to reason that we cannot give negative diagnoses on the strength of such extremely small samples as we usually examine On the whole, I think that in view of Lieutenant Bartlett's post mortem figures there was a vast amount of amœbic dysentery in the Mediterranean, even among persons in whom the disease was never diagnosed,

Now we must remember that hepatic abscess follows in a large proportion of amœbic infections, whether these infections have produced dysenteric symptoms or not On taking the histories of cases of hepatic abscess, we find no history of previous dysentery in something like a quarter of the cases—the probable truth being that the amœbic infection of the liver takes place from small intestinal pockets in which amœbæ had remained without causing widespread dysenteric lesions In fact, I have often thought that abscess follows the milder cases of dysentery more frequently than the severe ones Again, from some figures quoted by Rogers in the *Indian Medical Gazette* for November, 1912, we learn that the British army in India during the decade 1901–10 had one case of liver abscess for every seven cases of dysentery, more than 14 per cent If a similar proportion will be found to hold for Mediterranean dysentery, we can expect a very large number of cases of abscess

Prophylactic Treatment

PENETRATIVE WOUNDS OF THE ABDOMEN

A LIST OF THE FIRST FIFTY CONSECUTIVE CASES OPERATED UPON AT THE 17TH CASUALTY CLEARING STATION IN THE FIELD, FLANDERS

BY W C B MEYER, F R C S E,
CAPTAIN R.A M C (S R.)

AND

D C TAYLOR, F R C S,
LIEUTENANT R.A.M C

With a Note by

SURGEON GENERAL SIR ANTHONY BOWLBY, K C M G, A M S,
SURGEON-IN-ORDINARY TO H M THE KING CONSULTING SURGEON TO THE BRITISH EXPEDITIONARY FORCE IN FRANCE SURGEON TO ST BARTHOLOMEW'S HOSPITAL.

IT has been suggested to us that it might be of interest to publish results obtained by laparotomy for penetrative wounds of the abdomen and to quote actual cases We have, therefore, arranged in a tabular form certain facts about the first 50 cases operated upon. We also add the number of cases during this same period (three months) which have not been operated upon, either because they were mortally wounded and moribund, or because no perforation of the gut was suspected, or because they were expected to recover without operation No analysis has been attempted in this paper, as it is hoped that with larger experience more accurate conclusions will be able to be drawn and published at a later date We have merely stated our procedure in operation and have attempted to emphasise some facts which we have found to be important in dealing with these cases

Time between injury and operation —The cases have come to us wonderfully quickly from the firing line We have found that, generally speaking, the earlier a case is operated upon the better the chances of recovery The best results have been obtained where patients have been treated within 12 hours of being wounded

Preliminary procedure to operation —After admission the men are first of all rapidly and gently undressed and warmed up Rectal salines are not given where there is a risk of damage to the lower colon Morphia 1/4 gr and atropine 1/100 gr are administered subcutaneously as a routine before the anæsthetic, unless there be some contra indication, such as previous administration Laparotomy is generally performed about one hour after admission

Examination of the patient —A careful history is taken, especially with a view to discovering the course of the missile through the abdominal cavity It is generally possible to gain most valuable information as to the course of the missile by questioning the patient as to his own position when he was struck, his posture, his position in regard to the enemy, as to whether the missile came from above from below, from the side and so on

The man s general aspect is a very useful guide to the seriousness of his injury, the characteristic ashen grey colour of the face being of great importance Perhaps of all signs the condition of the pulse at the wrist is the most reliable index both of the man s condition and of the seriousness of the intra abdominal condition 1 Where it is absent altogether it is, generally speaking, almost hopeless to operate, not only because of the man's general condition, but because the seriousness of the lesions will almost certainly require lengthy operation 2 Where it is thready, running, and uncountable the prognosis is perhaps very grave but not hopeless as our results have shown, for extensive lesions requiring resection have in several instances been successfully treated 3 Where the pulse is stronger the prognosis, generally speaking, seems to improve according to the quality of the pulse

The usual symptoms and signs of intraperitoneal lesion, such as pain, tenderness rigidity and vomiting, are generally markedly prominent Even morphia does not, as a rule, completely disguise these, and in some cases no amount of morphia short of poisoning the patient appeared capable of overcoming pain Entire absence of rigidity where a perforation of the gut has certainly been present has been observed in moribund cases only

Where clinical signs and symptoms point to a perforation of the gut, even if, under anæsthesia, examination reveals no penetration of the peritoneum, we think it advisable to do a laparotomy as we have lost at least one case where the peritoneum was found to be intact and the track of the bullet was entirely extraperitoneal, and yet the bowel had been perforated This case would probably have been saved had we known that a bullet could cause a perforation of the gut without penetrating the peritoneum

The Operation

1 *Anæsthesia* —For purposes of anæsthesia chloroform induction followed by open ether has been invariably employed Subcutaneous saline under both breasts has been given as a routine whenever the pulse has not been really good From 1½ to 2 pints are generally administered from a Lane's indiarubber bag

2 *Incision* —The incision is planned to give most ready access to the area in which the lesions are calculated to be in We have most frequently adopted that through the rectus muscle increasing the distance from the mid line according to the situation of the lesion The incision has rarely been more than 4 to 5 inches in length

3 *Examination of peritoneal content and organs* —On opening the peritoneal cavity excessive blood and intestinal content are rapidly mopped away by gauze from a long roll The organs are then systematically examined, beginning with that suspected of being most damaged Any source of hæmorrhage or urgent lesion is dealt with immediately, otherwise we have adopted the principle of finding all the lesions before proceeding to their treatment By so doing precious time is saved, which may have been wasted in dealing with numbers of minor lesions when one large resection may have treated all the wounds rapidly, more surely, and with better prospects for recovery of the patient When perforations of the gut are met with they are at once covered by fourfold gauze and a light clamp is applied to prevent extravasation of content The examination of the rest of the abdominal organs is then proceeded with

4 *Treatment of lesions* —Small perforations or rents of the intestine are invariably sutured in the usual way preferably in the transverse axis of the gut or one is sutured thus and one longitudinally where there are two close together Resection is done (a) when there are rents involving

more than one third of the circumference of the gut, (*b*) when multiple rents or perforations lie very closely together, endangering the vitality of the operation area, (*c*) when the mesenteric edge of the bowel and the mesentery are both damaged, (*d*) when the mesentery has been badly torn, and (*e*) when the lesions are very numerous (to save time) It may here be said that it takes a shorter time to do a circular resection than to suture six or eight separate rents, and in our experience the shock and paresis following small resections are not greater than those accompanying multiple sutures Where larger resections are done—i e, over 10 to 12 inches—we have generally favoured lateral rather than circular anastomosis For all suturing of the gut we have used fine linen thread Bleeding wounds of the liver and spleen, where not too extensive, have generally been packed with gauze, removed on the third or fourth day In one extensive laceration of the liver two pieces had to be resected and the rents in the liver sutured with iodised catgut

5 *Treatment of peritoneal cavity*—After dealing with the various lesions, or best of all while the small gut is outside the abdomen, the peritoneal cavity is rapidly but carefully mopped as clean as possible, and where collapse is marked warm saline may be introduced into the peritoneal cavity with great benefit Wherever the gut has been perforated it is our belief that drainage of the peritoneal cavity for 24 to 48 hours is of undoubted value, not merely because a certain amount of infected fluid drains away, but because where we have not drained the discomfort of the patient after operation has been much more marked than where we have drained

6 *Treatment of the abdominal wall*—We have always first sutured the peritoneum and posterior sheath of the rectus with linen unless speed was urgently demanded, when silkworm gut through and through all layers was used The rest of the strata have then been stitched one by one, removing the local tension by two or three silkworm gut sutures through all layers except the peritoneum We have found it advisable to strap our sterile dressings to the abdomen by means of plaster to avoid exposure of wounds subsequently

After treatment

The usual post abdominal regime has been practised, such as warmth, Fowler position, &c Rectal salines four hourly are almost invariably given for 24–48 hours On the second or third day ½ c c of pituitrin is administered subcutaneously and 2 ounces of glycerine per rectum, repeated the following day if necessary In our experience the action of pituitrin is of inestimable value in promoting intestinal peristalsis About the fifth day an enema is generally given, except where the pelvic colon has been sutured Aperients are allowed on the eighth or ninth day, unless the bowels have moved freely of their own accord before, which has happened not infrequently Fluids, such as water, tea and sugar, and beef tea are given for the first three days water being allowed in sips when asked for immediately after operation Milk is added on the third day, milk puddings after the fifth day as a rule and chicken after the seventh day

Regurgitant vomiting is treated by stomach lavage repeated as often as necessary Persistent hiccough following larger resections has in our experience been relieved only by morphia or stomach lavage

Evacuation to the base—Patients have not generally been sent down to the base until out of danger—i e, when temperature and pulse had settled and were good, when the bowels had moved, when the tongue was clean and moist, and the patients were hungry

Results

Out of this series of 50 cases 17 deaths have occurred and 33 cases have been evacuated to the base We have heard from the majority of the cases since, as each man is requested to write to us in ten days' time and again in a month. We have heard of no subsequent deaths

Causes of death—From the sections we have been able to make certain that the cause of death in most cases of perforative abdominal lesions is primary hæmorrhage, combined with an element of shock always present in these cases Next in importance appears to be general peritonitis, which, however, takes from about 48 hours onwards to bring about a fatal issue A few cases seem to die from pure shock due to tissue damage inflicted by irregular shaped missiles without any degree of hæmorrhage (e g, kidney and liver in one case), a few others from secondary hæmorrhage into the bowel

Cases not Operated upon

The following cases were not operated upon during this period, because patients were moribund, because no perforation was suspected, or because conservative treatment was considered advisable —Total number, 41, died, 17, evacuated to base, 24

It is of interest that of the cases deliberately treated conservatively not a single case died, though the bullet had traversed the peritoneal cavity quite obviously in a number of these The indications for conservative treatment were always the general appearance of the patient, absence of shock, the condition of the pulse, the state of the abdomen, and the course of the bullet

In conclusion we beg to express our indebtedness to our commanding officers, Colonel Way and Lieutenant Colonel J W Langstaff, for permission to publish these notes, as well as for the constant encouragement and help they have afforded us at all times in dealing with these cases In particular we have to thank the consulting surgeon of our army, Surgeon General Sir Anthony Bowlby, and during his absence Colonel Cuthbert Wallace, for their inestimable advice and their unfailing zeal in coming to our aid so frequently and so regularly

NOTE BY SURGEON GENERAL SIR ANTHONY BOWLBY

The hospital in which the operations described above have been done is one of the Casualty Clearing Stations, and is in tents pitched beyond ordinary shell fire The arrangements for sterilisation are much the same as in a civilian hospital, and the theatre is lighted by acetylene gas Many of the operations have been done in the middle of the night

We have all learned a good deal since the war began but there is much yet to learn In the earlier days we were still under the influence of the South African War, and most surgeons believed that bullet wounds of the abdomen did best if left alone. That was also the opinion of many surgeons who had been in the Balkan War As time went on we had occasion to change our minds for we heard from the surgeons at the base

PENETRATIVE WOUNDS OF ABDOMEN TABULAR STATEMENT OF 50 CONSECUTIVE OPERATION CASES

No	Age	Wounds of entry and exit. Sector of abdomen above or below umbilicus	Missile	Special signs or symptoms Pulse	1 Lesions found at operation 2. Peritoneal content	Treatment: 1 Incision 2. Of lesion 3 Drainage of peritoneal cavity	Result and days in station	After results: Intra abdominal respiratory; abdominal wall	Necropsy Whether done operation area; lesions missed other facts
1	13	Entry: 1 in below and to left of umbilicus No exit, but bruise on left buttock from where bullet was extracted later Narrow sector below umbilicus	Bullet	Pulse 112, good.	1 Two perforations of jejunum 6 in from duodenum 2. About two ounces of small intestine content quite local and some blood	1 Left rectus 2. Perforations sutured. 3 Pelvis drained	Evacuated to base 10 days	Severe diarrhœa on fourth day marked bronchitis wound suppurated	—
2	13	Entry: 12th rib right posterior axillary line No exit. Wide sector above umbilicus	High explosive shell	Hæmatemesis Pulse 136, thready	1 Ragged tear in small curvature of stomach about 1½ in long Large hæmatoma in wall of hepatic flexure of colon also wounds of both arms and legs 2. Enormous amount of blood in peritoneum	1 Right rectus 2. Perforation in stomach sutured 3 Under surface of liver drained	Died 24 hours after operation suddenly	Patient died after an enormous stool of fresh blood evidently a secondary hæmorrhage from hepatic flexure	No necropsy
3	19	Entry: Left margin of rectus 2 in above pubis No exit Narrow sector below umbilicus	Bullet	Abdomen rather distended and very rigid Pulse 132 thready	1 Single perforation of iliac colon and a strangulated hernia of whole of movable small intestine into an enormous ileocæcal pouch 2. Small escape of colon content.	1 Left rectus 2 Perforation in iliac colon sutured Retroperitoneal hernia reduced sac ligatured and mouth of sac closed with sutures 3 Pelvis drained	Died 12 hours after operation	Patient died of shock largely due to length of operation and difficulty in dealing with strangulated hernia	No necropsy
4	19	Entry: 1 in below and to right of umbilicus Exit 3 in below and 3 in behind left anterior superior iliac spine Narrow sector below umbilicus		Pulse 120	1 Two perforations in ileum about 4 ft apart. 2. Much blood	1 Left rectus 2. Perforations sutured 3 Pelvis drained	Evacuated to base; 7 days	—	—
5	[illegible]	Entry: At umbilicus Exit Just below 12th rib left posterior axillary line Narrow sector at umbilicus		Very blanched Pulse 140 thready	1 No bowel lesion found Bullet had torn lower pole of left kidney in passing out of abdomen 2. Enormous amount of blood	1 Left rectus 2. Two stitches into lower pole of kidney and peritoneum closed over it 3 Lumbar wound opened up and drained	Died in 12 hours Shock and original hæmorrhage	—	No peritonitis or bowel lesion found No fresh hæmorrhage into abdomen
6	13	Entry: 6th and 7th rib right posterior axillary line Exit: 6th and 7th rib left midclavicular line Wide sector above umbilicus		No vomiting Pulse 120	1 Bullet had passed through liver and gastro-hepatic omentum missing small curvature of stomach by ¼ in 2. Much blood	1 Right rectus 2 Wound on under surface of liver packed with gauze 3 Gauze drain	Evacuated to base 6 days	—	—
7	21	Entry: between 6th and 7th rib (right) 3 in from mid line No exit Narrow sector above umbilicus	Revolver bullet (accidental)	Hæmatemesis Pulse 124	1 Liver perforated but neither wound bleeding A ragged tear about 1½ in long found in lesser curvature of stomach about 1½ in from the pylorus 2. Much escape of mucus and bile	1 Right rectus 2. Stomach tear sutured 3 Under surface of liver drained	Evacuated to base 9 days.	—	—
8	20	Entry Just below umbilicus Exit 2 in external to right anterior superior iliac spine Narrow sector below umbilicus	Bullet	Pulse 96.	1 Bullet had not entered peritoneal cavity but had caused a large extraperitoneal hæmatoma Just beneath line of injury small hæmorrhage into omentum 2. Nil	1 Right rectus 2. Nil 3 Abdomen closed	Evacuated to base 5 days	—	—
9	[illegible]	Entry Just to left of mid line half way between umbilicus and pubis No exit Narrow sector below umbilicus	Large rivet from accidental explosion	Very blanched Pulse 130 thready	1 Rivet embedded in mesentery of ileum at bowel attachment Small tear in peritoneal coat of bowel at same site Tear in mesentery 1 in long and mesenteric vessels still bleeding 2. Enormous amount of blood	1 Right rectus 2. Bleeding vessels ligatured and hole in mesentery closed Tear in peritoneal coat of ileum sutured 3 Pelvis drained	Evacuated to base 9 days	Marked bronchitis patient also had compound fracture of left radius and ulna near elbow joint	—
10	[illegible]	Entry 1½ in below and 1½ in to left of umbilicus No exit Narrow sector below umbilicus	Shrapnel	Very blanched Pulse 12[illegible], thready	1 Four perforations in jejunum found and two tears in small intestine mesentery the vessels of which were still bleeding 2. Enormous amount of blood	1 Left rectus 2. Perforations sutured Tears in mesentery sutured 3. Pelvis drained	Died in 15 hours Shock and original hæmorrhage	—	No necropsy
11	[illegible]	Entry 1 in below right anterior superior iliac spine Exit Bullet lying under skin 2 in above pubis and 1 in to left of mid line in anterior abdominal wall Narrow sector below umbilicus	Bullet	Pulse 120.	1 Three perforations in ileum; loop of jejunum 10 in long much damaged; slit longitudinally for 4 in and three other perforations in it 2. Much blood and small intestine content	1 Left rectus 2. Perforations in ileum sutured 10 in of jejunum resected and united by lateral anastomosis 3 Pelvis drained	Died 3 days after operation	Severe diarrhœa on second day; peritonitis	Necropsy Anastomosis sound; no lesions missed; very intense general peritonitis; coils of intestine [illegible] together

12	[illegible]	Entry: Just below right anterior superior iliac spine No exit Narrow sector below umbilicus		Very blanched; no pulse at wrist.	1 Ileum perforated in three places Ragged tear in mesentery of ileum 1½ in long Vessels still bleeding 2. Much blood	1 Left rectus; [illegible] line of incision lying in muscle 2. Perforations in ileum sutured; tear in mesentery sutured still pulseless on leaving table 3 Pelvis drained	Evacuated to base; 21 days	[illegible] in pelvis suppurated and patient developed signs and symptoms suggesting subdiaphragmatic abscess but these cleared up without further interference. Very severe hiccough for first 36 hours	—
13	19	Entry: 3 in behind left anterior superior iliac spine and 1 in below crest of ilium No exit Wide sector below umbilicus		Urine normal Pulse 100	1 Last loop of ileum perforated in three places Much local peritonitis 2. No bleeding Large escape of bowel content with marked fæcal odour	1 Left rectus 2 Perforations in ileum sutured and liquid fæces carefully mopped up 3 Pelvis drained	Evacuated to base; 10 days	Severe diarrhœa on second day; bronchitis Much discharge from pelvic drain	—
14	25	Entry: 8th rib left anterior axillary line Exit: 7th rib right mid axillary line Wide sector above umbilicus		On admission pulse 88; 3 hours later 120 and hæmatemesis	1 Two perforations in anterior wall of stomach 1½ in apart Tear on under surface of liver still bleeding Falciform ligament distended with blood 2. Blood and gas from stomach	1 Left rectus 2. Perforations in stomach sutured Wound on under surface of liver packed with gauze 3 Gauze drain	Evacuated to base 6 days	—	—
15	14	Entry 10th rib mid axillary line No exit Wide sector above umbilicus	High explosive (bomb)	Very frequent vomiting Pulse 120	1 Tear on right side of liver 2. Much blood	1 Right rectus 2. Liver wound packed with gauze 3 Gauze drain	Died 5 days after operation	Patient died quite suddenly with symptoms suggesting secondary hæmorrhage	No necropsy
16	22	Entry: Just below 12th rib in left mid axillary line No exit. Wide sector above umbilicus	High explosive shell	Pulse 120	1 Large tear in anterior wall of descending colon 2 Some escape of fæcal matter	1 Left rectus 2 Perforation stitched Transverse colotomy 3 Drainage through lumbar wound	Evacuated to base; 5 days	—	—
17	23	Entry: 7 8th rib left posterior axillary line No exit Wide sector above umbilicus	Shrapnel	Very blanched Pulse 132	1 Tear in lower angle of spleen No other lesion found Profuse bleeding 2 Enormous amount of blood	1 Left rectus 2 Spleen tightly packed with gauze 3 Gauze drain	Evacuated to base 9 days	Packing around spleen removed on fourth day after operation No fresh bleeding	—
18	42	Entry: Right posterior axillary line 1 in below crest of ilium Exit: Left groin close to pubic spine Narrow sector below umbilicus	Bullet	Profuse hæmaturia On admission pulse 96; 12 hours later 120	1 Two perforations in last loop of ileum; marked peritonitis Posterior wall of bladder bruised but not perforated 2 Much escape of bowel content with marked fæcal odour	1 Right rectus 2 Perforations stitched 3 Pelvis drained	Died 12 hours after operation Shock and peritonitis	—	No necropsy
19	30	Entry: Three wounds between left 12th rib and iliac crest No exit Narrow sector below umbilicus	Shrapnel	Pulse 128	1 No lesion found except bruise in omentum 2 Small quantity of free blood in peritoneum	1 Left rectus 3 Abdomen closed	Evacuated to base; 3 days	—	—
20	35	Entry: 1 in below sternum and just to right of mid line No exit Narrow sector, above umbilicus	Bullet	Very pale Pulse 120	1 Large tear on anterior surface of liver; bleeding profusely also from tear on under surface Bullet passed through gastro-hepatic omentum just missing stomach 2 Much blood	1 Right rectus 2 Liver packed with gauze 3 Gauze drain removed on fourth day	Evacuated to base; 6 days	—	—
21	37	Entry: Over left posterior superior iliac spine Exit: Bullet lying under skin 2 in above pubis just to left of mid line Narrow sector, below umbilicus	Shrapnel bullet	Pulse 120	1 Four perforations in ileum and two in jejunum Mesentery uninjured 2 Little blood	1 Left rectus 2 Perforations in ileum and jejunum sutured 3 Pelvis drained	Evacuated to base 8 days	Bronchitis	—
22	21	Entry: ½ in below and 1 in to right of umbilicus Exit: 2 in above iliac crest mid axillary line Narrow sector below umbilicus	Shrapnel	From exit wound large amount of liquid fæcal matter was escaping Pulse 120	1 Loop of ileum perforated in two places lower tear 3 in long also small tear in mesentery of ileum 2 Small intestine content locally No blood	1 Incision over track of missile 2 10 in of ileum resected and end to-end anastomosis done 3 Peritoneum drained locally through posterior angle of wound	Evacuated to base; 7 days	Bronchitis Much suppuration of abdominal wound	—
23	30	Entry: Right mid axillary line half way between last rib and crest of ilium No exit Narrow sector below umbilicus	High explosive shell	Pulse 100	1 Irregular piece of copper band found embedded in wall of ascending colon Lumen of bowel not opened 2. Little blood	1 Right rectus 2. Peritoneal tear in ascending colon sutured 3 Drained through wound of entrance	Evacuated to base; 6 days	Bronchitis	—
21	21	Entry: Left linea semilunaris 1 in below umbilicus No exit. Wide sector below umbilicus	Bullet	From entrance wound there was extruded a small loop of small intestine covered with omentum Pulse 140, thready	1 Loop of jejunum 12 in long found perforated in six places and nearly severed in two places Knuckle of bowel protruding through wound was also bruised but uninjured 2. Much blood	1 Left rectus 2 Bullet not found 1 ft of jejunum resected and end to-end anastomosis done Piece of extruded omentum ligatured and removed Pulseless on leaving table 3 Pelvis drained	Evacuated to base 11 days	Bronchitis Suppuration in entrance wound	—

PENETRATIVE WOUNDS OF ABDOMEN TABULAR STATEMENT OF 50 CONSECUTIVE OPERATION CASES—(*Continued*)

	Age	Wounds of entry and exit Sector of abdomen above or below umbilicus	Missile	Special signs or symptoms Pulse	1 Lesions found at operation 2 Peritoneal content	Treatment: 1 Incision 2 Of lesion 3. Drainage of peritoneal cavity	Result and days in station	After results: Intra abdominal respiratory abdominal wall	Necropsy: Whether done operation area lesions missed other facts
[illegible]	19	Entry: ½ in below right anterior superior iliac spine No exit Wide sector below umbilicus	Bullet	Pulse 140 thready	1 Ileum nearly divided across Loop of jejunum close to duodenum perforated in six places nearly across in two places Bullet found lying free on omentum near lower border of stomach 2 Much blood	1 Right rectus 2 4 in of ileum resected end-to-end anastomosis 18 in of jejunum resected end-to-end anastomosis Pulse 140 on leaving table 3 Pelvis drained	Died 18 hours after operation	—	Necropsy Resections perfect Transverse colon near splenic flexure found to have three perforations in it Also tear in transverse meso-colon Marked general peritonitis
[illegible]	20	Entry Left linea semilunaris just below umbilicus No exit Narrow sector below umbilicus	Shrapnel	Pulse 112	1 Single perforation in jejunum Missile not recovered 2 Some blood	1 Left rectus 2 Perforation in jejunum sutured Pulse 120 on leaving table 3. *Pelvis drained*	Evacuated to base; 8 days	Bronchitis Some suppuration in lower angle of wound	—
27	20	Entry: At tip of coccyx Exit: Large wound just below and to right of umbilicus Wide sector below umbilicus	Bullet	From exit wound large piece of omentum was extruded Pulse 140 thready	1 Loop of ileum 20 in long perforated in seven places Ileum perforated in two other places One perforation of jejunum Two perforations in iliac colon one perforation in rectum very low down 2. Much blood	1 Left rectus 2. Loop of ileum 20 in long resected end to end anastomosis Perforations in ileum jejunum iliac colon and rectum sutured 3 Pelvis drained	Died 12 hours after operation	—	Necropsy Sutures and resection apparently perfect. Very little peritonitis No fresh hæmorrhage Patient died from shock and hæmorrhage
[illegible]	30	Entry: Loin left side touching [illegible]th rib scapular line Exit: Nil Course: Posterior abdominal wall above umbilicus	Shrapnel	Hæmaturia No vomiting Pulse under 120 moderate quality	1 Kidney perforated 2. Full of blood	1 Centre of left rectus 2 Drainage of posterior wound 3 Peritoneal cavity not drained	Evacuated to base; 7 days	Urinary fistula posteriorly sixth day	—
[illegible]	33	Entry: Loin left side through 12th rib ½ in from mid line Exit: Bullet lodged at epigastrium under skin midway between xiphisternum and umbilicus Narrow sector above umbilicus		Hæmaturia. Vomiting marked Pulse 140 poor	1 Perforation of kidney and jejunum two rents 2 Blood in quantity No escape of intestinal content	1 Left rectus 2 Drainage of posterior wound suture of perforations 3 Peritoneal cavity drained	Death in 14 days Toxæmia of suppuration in wound	Slight bronchitis B coli suppuration in abdominal wall	No necropsy Doubtful if all lesions treated
[illegible]	[illegible]	Entry: Left hypochondrium centre on mid-clavicular line; omental tag protruding Exit: Nil Narrow sector above umbilicus	Rifle bullet	Hæmaturia; marked hæmatemesis Pulse uncountable thready and very feeble	1 Stomach two rents one on anterior and one on posterior wall Jejunum four holes (rents) Left kidney perforated 2 Blood stomach content gas and small intestinal content in greater and lesser sacs	1 Mid line 2 Suture of stomach resection of 3 in of jejunum circular anastomosis 3 Drainage + of lesser sac	Evacuated to base 11 days	Slight bronchitis	—
[illegible]	[illegible]	Entry: Left 1 in; large laceration 1½ in across fracturing [illegible]th rib Exit: Nil Course: Posterior abdominal wall above umbilicus	High explosive shell fragment	Hæmaturia; hæmoptysis; vomited twice Pulse 1[illegible]0 poor	1 Left kidney lacerated; good deal of hæmorrhage Rent in posterior peritoneum 2 Blood in quantity	1 Left rectus 2 Packing of posterior wound 3 Not drained	Evacuated to base 5 days Improved in general condition	Fæcal fistula third day Slight bronchitis	—
[illegible]	[illegible]	Entry Left 1 in posteriorly [illegible] in above crest ilium scapular line Exit Nil Course [illegible] posterior abdominal wall above umbilicus	Whizz bang shell fragment	No vomiting Pulse 110 good	1 No intraperitoneal lesion found 2 Blood in quantity	1 Left rectus 2. Drainage of loin wound 3. Peritoneal cavity not drained	Evacuated to base; 8 days	Fæcal fistula second day from posterior wound Slight bronchitis Fæcal escape from anterior wound third day	—
[illegible]	[illegible]	Entry 1½ in to right of umbilicus and slightly below Exit Nil Wide sector below umbilicus	Rifle bullet	Vomiting present Pulse thready and feeble	1 Jejunum five rents over 8 in of gut Ileum three rents in 3 in of gut and one isolated rent 2. Blood in quantity Small intestinal content	1 Right rectus. 2 9 in jejunum resected lateral anastomosis 4 in ileum resected circular anastomosis Suture of isolated rent 3 Drainage	Evacuated to base 16 days	Bronchitis Suppuration of wound necessitating secondary suture	—
[illegible]	[illegible]	Entry 1 in above anterior superior spine 1 in external to [illegible]axillary line left side Exit Nil Wide sector below umbilicus		Vomiting present Normal pulse	1 Ileum one isolated perforation four rents in 4 in of gut Descending colon fixed portion one rent 1 in long 2 Blood in large quantity Small intestinal content At least [illegible] [illegible] matter	1 Just external to left rectus 2. Suture of isolated perforation Resection [illegible] in ileum circular anastomosis. Suture of rent in colon 3 Drainage	Death 23 hours later General peritonitis and shock	Regurgitant vomiting	Necropsy All [illegible] satisfactorily dealt with Early general peritonitis

[illegible]	[illegible]	Entry: Lacerated wound through [illegible] rib right [illegible] back just [illegible] spine Exit: Nil Wider sector above umbilicus	Whizz bang shell fragments	Hæmaturia. Vomiting present Pulse thready just perceptible	1 Kidney soft upper pole rent made out Liver damaged 2. Small amount of blood stained bile	1 Right rectus 2. Nil 3 Not drained	Death 21 hours later Shock	—	Necropsy Upper third of kidney badly lacerated; also right lobe of liver Shell fragment 1¼ in long removed from liver
7	[illegible]	Entry: Two small wounds left [illegible] axillary line just [illegible] anterior superior spine Exit: Nil Narrow sector below umbilicus	Trench mortar shell fragments	Vomiting present Pulse 120 feeble	1 Jejunum two perforations 2. Turbid fluid in peritoneal cavity	1 External to left rectus. 2. Suture of two perforations 3 Not drained	Evacuated to base; 8 days	Good deal of pain Bronchitis	—
57	22	Entry: Right buttock centre at gluteal fold Exit: Nil Wider sector below umbilicus	High explosive fragment	Vomiting present Pulse 120 moderate	1 Ileum four perforations mesentery four perforations and two contusions 2 Purulent and feculent fluid in peritoneal cavity	1 Mesial incision 2 Resection of 2½ in ileum circular anastomosis. Invagination of contused mesentery 3 Drainage	Evacuated to base 6 days	Slight bronchitis	—
[illegible]	13	Entry: Multiple back one just below 11th rib right side deep Exit: Nil Above umbilicus	Shrapnel	Vomiting present Hyperæsthesia over right side of abdomen and back Pulse 120 moderate under $CHCl_3$ down to 80 and good	1 Nil 2. Nil	1 Right rectus 2 Nil 3 Not drained	Evacuated to base 5 days	—	—
[illegible]	25	Entry: Epigastric 1 in to right and 2 in above umbilicus Exit: Nil Narrow sector above umbilicus	Rifle bullet	Vomiting present. Pulse 110 moderate	1 Jejunum two large rents involving mesenteric border Large bleeding rents in great omentum 2. Blood and intestinal content	1 Right rectus. 2 Jejunum resection 4 in circular anastomosis Omentum sutured 3 Not drained	Evacuated to base 36 days later	Serious and obstinate purulent bronchitis Marked suppuration of wound necessitating secondary suture 19 days later	—
9	8	Entry: Epigastric ½ in to left of mid line 2 in from xiphisternum Exit: Nil Wider sector above umbilicus	High explosive	Vomiting present Pulse thready barely perceptible	1 Jejunum: (*a*) Four small perforations isolated (*b*) In 8 in of gut five rents two rents of mesentery (*c*) In 3 in of gut two large rents In great omentum one rent. 2. Blood small intestinal content lymph in quantity	1 Right rectus 2 Jejunum: (*a*) Four holes sutured (*b*) Resection 9 in circular anastomosis (*c*) Resection 4 in circular anastomosis 3 Drainage	Death 5 hours later Shock and hæmorrhage	—	Necropsy All lesions dealt with
11	24	Entry: Left buttock Exit: About midway between umbilicus and symphysis rent 1 in in diameter Wider sector below umbilicus	Rifle bullet	Vomiting present Pulse thready barely perceptible	1 Ileum: (*a*) In 20 in of gut ten perforations and rents of various sizes and shapes (*b*) Isolated rent Mesentery: One large rent, bleeding 2. Blood gas small extravasation fæcal matter	1 Left rectus 2. Ileum: (*a*) 21 in resected lateral anastomosis (*b*) Suture of isolated rent. 3 Drainage	Evacuated to base 13 days	Marked hiccough regurgitant vomiting Bronchitis B coli suppuration in exit wound secondary infection of sutures No need for secondary suture	—
42	20	Entry: 1 in to left of mid line just below 12th rib Exit: Nil Wider sector above umbilicus	Shrapnel bullet	Sighing rapid catchy respirations Vomiting Pulse absent at first three hours later just perceptible	1 Diaphragmatic rent 2 in long Hernia of 3 or 4 ft. of jejunum through diaphragm one coil of which four perforations splenic flexure colon two rents 2. Blood in large quantity	1 Mesial incision 2nd oblique from umbilicus to lower costal margin 2. Suture of diaphragm not complete operation abandoned patient moribund	Death half hour later Shock and hæmorrhage	—	Necropsy Great omentum spread over base of left lung Bullet removed from left lung
43	[illegible]	Entry: Just below 12th rib posterior axillary line Exit: 1 in below xiphisternum mid line Wider sector, above umbilicus	Rifle bullet.	No vomiting Pulse 84 rose to 110 in 24 hours during which he was watched	1 Liver perforated and bleeding Gastro-hepatic omentum scored 2 Blood and bile in large quantity	1 Right rectus 2 Liver packed to stop hæmorrhage 3 Drainage	Evacuated to base 10 days	Delirious for 48 hours Vomiting Marked bronchitis	—
44	19	Entry: Left hypochondrium below costal margin anterior axillary line Exit: Nil Narrow sector above umbilicus		No vomiting Pulse 90, good	1 Bullet lodged behind peritoneum below spleen Palpated with ease 2. Nil abnormal	1 Outer side left rectus 2. Bullet left *in situ* 3 Drainage	Evacuated to base 6 days	—	—
45	21	Entry: McBurney's point right side lower abdomen Exit: Nil Wider sector below umbilicus		Vomiting present Pulse 80 good	1 Ileum perforated in six places bullet peeping through one coil having just penetrated 2. Purulent fluid as in suppurative appendicitis	1 Outer side right rectus 2 Ileum suture of six perforations Appendectomy 3 Drainage	Evacuated to base 6 days	Slight bronchitis	—
46	23	Entry: Multiple wounds back One on right side below 12th rib 1½ in from mid line admitting whole length of forefinger towards peritoneal cavity Exit: Nil Non penetrative above umbilicus	High explosive	Vomiting present. Pulse 130 feeble	1 Piece of shell and clothing removed lying in contact outer side of peritoneum left loin 2 Nil abnormal	1 Right rectus 2. Wounds cleansed Pieces of shell removed 3 Peritoneal cavity not drained	Evacuated to base 8 days	No bronchitis	—

PENETRATIVE WOUNDS OF ABDOMEN TABULAR STATEMENT OF 50 CONSECUTIVE OPERATION CASES—(*Continued*)

No	Age	Wounds of entry and exit Sector of abdomen, above or below umbilicus	Missile	Special signs or symptoms Pulse	1 Lesions found at operation 2. Peritoneal content	Treatment: 1 Incision 2. Of lesion 3 Drainage of peritoneal cavity	Result and days in station	After results: Intra abdominal respiratory abdominal wall	Necropsy: Whether done operation area lesions missed other facts
47	30	Entry: 1 in below and 1 in to left of umbilicus Exit: Nil Narrow sector below umbilicus	Rifle bullet	No vomiting Pulse 100 good	1 Ileum, three perforations *mesentery* one perforation two bruises 2. Blood in quantity	1 Left rectus 2 Ileum perforations sutured mesentery hole sutured, bruises invaginated 3 *Drainage*	Evacuated to base 7 days	Bronchitis	—
48	31	Entry: Right buttock just posterior to great trochanter 1 in below tip Exit: Nil Wider sector below umbilicus	"	Hæmaturia. Vomiting present. Flicker occasionally otherwise pulseless.	1 Ileum: (*a*) One isolated perforation (*b*) Ten perforations and rents in 13 in small intestine Mesentery Four large rents bleeding still 2. Blood and small intestinal content	1 Mid line 2. *Ileum* (*a*) *Single* perforation sutured (*b*) 14 in resected lateral anastomosis 3 Drainage	Death *half* hour later Shock and hæmorrhage previous to operation	—	Necropsy Sutures satisfactory No lesions missed Side of bladder contused
49	21	Entry: McBurney's point right lower abdomen Exit: Bullet lodged under skin left buttock Wider sector below umbilicus	Shrapnel bullet	*Vomiting present No* radial pulse	1 *Pelvic colon two rents* Ileum 11 rents in 44 in necessitating three different *resections or one* large one Mesentery five different rents 2. Blood small intestinal content, gas	1 Right rectus 2. Pelvic colon sutured Ileum 44 in resected *Ileocolostomy end to side just* above cæcum 3 Drainage	Death while suturing wall of abdomen Shock and previous hæmorrhage	—	Necropsy Operation area satisfactory No lesions missed
50	5	Entry: Just below xiphisternum and 1 in to right of mid line Exit: Nil Wider sector above umbilicus	High explosive fragment.	Vomiting present No radial pulse	1 Liver badly lacerated Stomach rent in lesser curvature Gastro hepatic omentum torn Duodeno jejunal flexure two rents 2. Blood bile intestinal content	1 Mid line 2. Stomach rent sutured Liver two torn fragments 1 in square resected; sutured Jejunum sutured 3 Drainage	Death 8 hours later Shock and hæmorrhage	—	Necropsy Operation area *satisfactory* Two holes in third part of duodenum missed

that many of our patients who seemed to be doing well ultimately died from peritonitis, and we also found by making post mortem examinations that the lesions of the viscera were generally so severe and extensive that they could not possibly repair themselves We further found that hæmorrhage from vessels which could have been tied was a common cause of death, and we also noticed that in many cases of injury of the small intestine there was very little immediate escape of contents and soiling of the peritoneum, *so that the conditions* for operation were better than we had expected

It is easy enough now to realise these facts, but preconceived ideas die hard, and early in the war there was too great a rush of events to give time for investigation *During* the retreat, and the battles of the Marne and the Aisne, the various medical units had more work than they could well do, and in the fierce fighting at Ypres we were always struggling with even larger numbers of wounded In spite of these difficulties a certain number of abdominal operations were done, but the results obtained rather deterred than encouraged the operators It was not till this period was passed that it became possible to equip the casualty clearing stations for their new rôle as emergency hospitals and to make post mortem examinations Early in the past year Captain Owen Richards had several successful cases of intestinal resection and suture, and during the ensuing spring and summer more and more cases were operated upon with *gradually increasing success*, so that ultimately for the past five or six months it has come to be the custom to look upon all abdominal wounds as probable cases for operation

The effect of this new outlook has been that instead of patients being kept in field ambulances they are despatched as speedily as possible to the casualty clearing stations, and I have seen patients on the operating table within two and a half hours of being hit in the trenches, and just in time to save life from hæmorrhage

The essentials for success in operations upon gunshot wounds of the abdomen may be briefly stated as follows —1 Rapid transport to hospital 2 Suitable antiseptic and aseptic conditions for operation 3 *Good nursing and suitable feeding* 4 *Opportunity for* retaining the patient for at least a week or 10 days before evacuation

I am altogether opposed to the idea of operating in "dug outs" or ruined houses close to the trenches, or in field ambulances which may have to be suddenly emptied In the former the conditions necessary for success in the operation itself cannot be provided, and in neither can the patient be kept as long as is essential if he is *to be given* the best chance of recovery *It may* be admitted that it is not a good thing for a wounded man to have to be driven several miles before an operation is done, but it must be also realised that it is a much worse thing to drive him the same distance directly *after an operation*, and, as he cannot be left indefinitely in a dug out or a field ambulance, the sooner his journey is started and got over and the earlier he gets to a place where he can remain the more chance will the surgeon have of doing his best for his patient

Both post mortem examinations and operations have convinced everyone that the majority of patients who die with perforating abdominal wounds die from hæmorrhage and we are all also agreed that if the intestine is opened by a bullet or shell fragment the patient will almost certainly die from peritonitis if he does not die from [illegible]

The reason for this opinion is not based merely on clinical observations, but on the very extensive and numerous lesions which are so often found, and which are well illustrated in the present paper We have also learned by operations that both bullets and shell fragments may traverse the intestinal area without wounding the bowel, and that many wounds which appear to perforate do not really do so Another striking fact of much practical importance is that no less than 24 wounds out of the total of 50 were due to missiles which entered the flanks or the gluteal region, while in other cases the wound of entry may be through the chest or even through the shoulder or neck

It will be noticed that out of a total of 91 patients admitted 41 were not operated upon, 17 of them because they were past help, and the remaining 24 because it was not considered necessary All of the latter recovered—a fact which demonstrates that selection is justifiable My own advice has been that all wounds without exception which seem likely to involve the area of the small or large intestine should be subjected to an exploratory operation, and that a laparotomy should be done if the peritoneum is found to have been involved Operation should also be done in all those wounds of the gluteal and lumbar regions where the symptoms point to a visceral lesion I do not advise operation in the epigastric or hepatic regions, especially in antero posterior wounds, if there are no definite symptoms, but if there is evidence of continuing bleeding then operation should be undertaken The same holds good of the renal and splenic regions, but it is too early to regard these opinions as final

It will be seen that the intestines or the stomach were wounded in 34 cases out of the total of 50, and that of these patients no less than 21 recovered in spite of multiple perforations in many cases and of serious injury to other viscera as well Resection appears at first sight to be much more fatal than suture, but it must be remembered that the injuries which necessitated resection were also much the more serious and that the patients were far more ill

It may fairly be claimed that in all the cases of wounds of the intestine and in most of the others who recovered the lives of the patients were saved by the operation

THE TREATMENT OF "CONCUSSION BLINDNESS"

By ARTHUR F HERTZ, M D Oxon, F R C P Lond,
MAJOR R A M C

AND

ARTHUR W ORMOND, F R C S Eng, L R C P Lond,
CAPTAIN R A M C (T)

ONE of the principal ocular features of the present war is the number of cases of functional blindness due to the violent explosions caused by high explosive shells, bombs, hand grenades, &c These cases may or may not have sustained definite organic injuries, but the clinical symptoms characterising their functional nature are very clearly marked Usually the patient has been rendered unconscious by an explosion in his close vicinity, and on regaining consciousness he finds that he is unable to see When examined he presents the following symptoms The eyes are kept closed the lids may be frequently 'fluttered' or as one man stated he could not keep his eyes from twinkling On attempting to open the lids the patient resists forcibly by means of his orbicularis, when this is overcome to a sufficient extent to see the globes, they are found to be rolled forcibly upwards, and the pupils are always kept covered by the lids, he has great difficulty in looking downwards, and complains of pain and photophobia, and shows marked fatigue as a result of the examination. In some cases I (A W O) have noticed an acceleration of the pulse rate and also perspiration The photophobia is not, however, really influenced by light, as the condition does not diminish in very subdued illumination These patients never move about as blind men would, they invariably avoid hurting themselves, but all the same they never relax, even if watched for weeks at a time, the groping action of people with extremely defective sight, and judged by every test they maintain this condition indefinitely and are undoubtedly psychically blind The pupils react normally and the fundus shows no definite change There is no difficulty in differentiating them from malingerers, as they pass through long periods of real mental distress and serious discomfort These cases vary enormously in severity, some recover rapidly, others seem to go on indefinitely if not treated, or treated unsuccessfully Any lack of recognition of the condition in the early stages enormously prejudices the prognosis One patient having been told that he was blind remained so for several months, whereas probably if it had been recognised earlier that he was not blind and would recover he would have done so much more rapidly

Early in the war I treated these cases in several ways, all with disappointing results, some of the slighter cases certainly did recover, but they recovered in spite of treatment and not on account of it The main principles on which I worked were rest, tonics, deprivation or punishments such as abstention from tobacco, confinement to bed or in isolation rooms, persuasion, encouragement, counter irritation, talking, &c, but all these means were comparatively ineffective until suggestion and hypnosis were tried In August, 1915, I thought it would be advisable to try suggestion, although I had a strong personal prejudice against its use, but when later on these cases still remained on my hands I consulted with Dr Hertz, and we decided to start the hypnotic treatment The method employed was to have the men singly in a darkened room, quiet, and resting in the most comfortable armchair the ward could provide They were instructed as to what was to be attempted, and no demur was ever made by any of them, but, on the contrary after the first experience they were always eager to continue the treatment The patient had his eyes closed, of course, so that the assistance of light and fixation could not be obtained, but he was told to think of something pleasant and agreeable, not to take the slightest notice of the operator, to relax his mind by attempting to stop all incoming thoughts and to make his mind as far as *possible*, a blank We then used the usual methods of inducing hypnosis In some cases—for example, Case 1—the hypnotic condition was obtained, but not in all, and I do not think it at all necessary to obtain complete unconsciousness, the main thing to be arrived at is to obtain a relaxation of the patient's mind and his muscles and to overcome his unconscious resistance

The treatment is carried on thus for a few minutes, and having obtained the sleepiness or light hypnosis necessary, the patient is subjected to a forcible suggestion from the operator, who reiterates the patient's ability to see and to open his eyes and to assert very vehemently that he is not blind as he imagines, but that his eyes are perfectly sound and that he *can* see

The results have varied considerably as to rapidity of recovery, but all have shown marked improvement, the most drastic being that of the patient in Case 1 the most resistant being the deaf and blind man (Case 5) Cases of this nature have been constantly arriving from France and Gallipoli, but I here insert the notes sent to me by Dr Hertz immediately previous to his departure for Alexandria, as they were the earliest ones with which we dealt and are quite typical, and in all of them, except in the last case, Dr Hertz collaborated with me in their treatment, they, however, only represent a small proportion of the total number of cases

Notes of Cases by DR. HERTZ

CASE 1 —The patient, aged 22, was looking over a parapet on July 18th, 1915 when a shell struck the sandbags in front of him He remembers the sand being thrown up into his eyes and his falling back so that he knocked his head He remained unconscious for 24 hours When he regained consciousness he found that he was completely blind, except that he could just distinguish light from darkness with his left eye His eyes felt very sore and his eyelids were constantly moving up and down he was partially deaf and had a severe headache His hearing soon returned, and the headache rapidly improved, but the condition of his eyes had not altered when I first saw him with Mr Ormond on Sept 17th He was quite blind and there was a constant flicker of his eyelids, which were kept almost closed On forcibly opening his eyes they were found to be turned so far upwards that it was difficult to see even the iris A few fragments of sand were still embedded in the conjunctiva but not in the cornea, there was no inflammation present

The patient was easily hypnotised, and whilst asleep he was told that he would be able to see when he woke up The moment he awoke the suggestion was repeated very forcibly, and his eyes were held open He cried out that he could see, tears ran down his cheeks, and he fell on his knees in gratitude, as he thought that he was permanently blind and believed that his sight had been restored by a miracle When seen again on Sept 20th the external appearance of his eyes was normal, and he said that he was able to see as well as he had ever done Mr Ormond however, found that there was some opacity of the vitreous of the left eye secondary to hæmorrhage from a retinal vessel which had ploughed its way forward, this was doubtless a result of injury at the time of the explosion There has been no return of symptoms and the patient was well in every way when I last saw him on Sept 30th His vision was 6/6 in the right eye and 6/36 in the left

CASE 2 —The patient had an attack of blindness resulting from conjunctivitis caused by a sandstorm when in Egypt early in 1915 He recovered from this after ten weeks, and six weeks later went to the Dardanelles On July 12th a shell struck a sandbag immediately in front of him and the sand flew into his eyes He did not lose consciousness but his sight gradually became more and more deficient until at the end of ten days he was only just able to distinguish light from darkness Very slight improvement occurred spontaneously but his condition when seen on Sept 17th was identical with that of the patient in the preceding case, a few pieces of grit being still embedded in the conjunctiva although there was no inflammation

The patient was easily hypnotised but there was very little improvement at the moment Considerable improvement however occurred during the next three days He was hypnotised on three more occasions he could see perfectly well on Sept 30th but still had some photophobia and wore dark glasses as he could not avoid constantly blinking when they were removed He was therefore hypnotised once again and it was suggested to him that the photophobia and blinking would now cease The result was completely successful as all symptoms had disappeared by Oct 4th, although no attempt had been made to remove the grit from the conjunctiva

CASE 3 —The patient, aged 20 was rendered unconscious for a few minutes as a result of the explosion of a shell near him on August 21st in the Dardanelles Some of the powder was blown into his eyes, which were very sore when he regained consciousness, although he was still able to see quite well During the next 24 hours his vision became more and more impaired The powder was removed from his eyes when he was taken on board the hospital ship and his eyes were bandaged After a few days he thought he would be able to see quite well if the bandages were removed but the medical officer in charge told him that it would be dangerous to do so During the voyage home he was not allowed to remove the bandages and he became more and more convinced that this must be because the medical officer thought he was blind The bandages had not been removed when he was admitted into the hospital on Sept 25th When they were removed he was found to be in exactly the same condition as the preceding patients He could distinguish light from darkness, but was unable to see anything and he kept his eyes turned up and his eyelids closed and constantly contracting

On Sept 27th he was hypnotised by Mr Ormond after which he found that he could see quite well but the light still worried him and the blinking continued, though to a diminished extent He completely recovered subsequently and returned to his depot

CASE 4 —The patient aged 29, was knocked over by a high explosive shell in the Dardanelles and remained unconscious for a considerable time On coming round he found he could only distinguish light from darkness, there was no smarting of the eyes, but he constantly blinked He had a slight headache, but was otherwise well He began to improve about Sept 10th, so that he could recognise shadows passing in front of his eyes, but no further improvement occurred until he was hypnotised on Sept 18th There was very slight improvement as the result of suggestion at the time, but when seen again on the 20th he said that he was beginning to recognise objects and the blinking was less marked than before, but he still kept his eyeballs turned upwards and his eyes almost closed He was hypnotised again on Sept 20th and 25th, and when seen on the 30th his sight was quite normal and the blinking had completely ceased Subsequent retinoscopic examination revealed the presence of a considerable degree of myopic astigmatism in the right eye and mixed astigmatism in the left

CASE 5 —The patient was signalling from a gun limber on April 28th when he was blown up and remained unconscious for six days There was no external wound but on regaining consciousness he found that he was blind except that he could just distinguish light from darkness, he was also completely deaf and was unable to speak He regained his speech in June, after a fortnight's treatment by hypnotism at Plymouth but his sight and hearing remained unaltered

When I saw the patient on Sept 17th he could only be made to hear by shouting down an ear trumpet, he kept his eyelids almost closed and constantly twitching with his eyeballs turned upwards He was extremely depressed as he had been told by an aurist that he would never regain his hearing as it was said that nerve deafness of such long duration could not improve although the drums were intact He concluded that the blindness would also be permanent It was not easy to hypnotise him as he was unable to see and all suggestions had to be shouted down his trumpet but Mr Ormond succeeded in doing this at the first attempt When seen on Sept 20th he said that his sight was distinctly better and he was able with difficulty to open his eyes He was much more cheerful particularly when we told him that his hearing would also return as his auditory nerves were no more organically diseased than his optic nerve On Sept 29th there was some further improvement as he could see everything in the outer part of his left field of vision fairly well He was having a good deal of domestic worry which no doubt prevented a more rapid improvement

CASE 6 —The patient was unconscious for [illegible] after being blown up by a shell on August 7th He was unable even to distinguish light from darkness when he recovered consciousness but he very gradually improved He was admitted into the hospital on August 22nd after which his [illegible] was much more rapid and by the end of Sept when he had quite recovered [illegible]

CASE 7 —The patient aged 20 had never [illegible] left eye owing to an extreme degree of hypermetropia [illegible]

When the other eye was covered he could only see very indistinctly with it but in spite of this he managed to pass the medical examination when he entered the army He was hit on the left side of the head by the butt of a rifle in June and was unconscious for a few minutes When he regained consciousness he at once noticed that he could not see at all with his left eye, although he had hitherto been in the habit of neglecting the blurred image he saw with this eye On August 10th he received a slight wound to his left thigh, but continued on duty The wound had not completely healed, and was still somewhat painful when on August 23rd he was blown up by a high explosive shell When he regained consciousness he was being carried on a stretcher The pain from his old wound drew his attention to his left leg, and he thought that he was unable to walk. When taken on the ship he found that this was the case, although there was no new injury of the leg He also complained of severe pain above the left eye which he kept covered by a shade, as he found that the least light greatly increased the headache, when the shade was removed he was unable to open the eye at all For some time he was in an extremely excited condition and he slept very badly owing to nightmares His eye was kept covered by a shade during his journey home from the Dardanelles On his arrival in England Mr C M Ryley found that beyond the hypermetropia his left eye was normal, although he was quite unable to see anything with it

The patient was hypnotised on four different occasions After the first he already slept better the nightmares ceasing and the headache being less severe. On the second occasion whilst still asleep the shade was removed from his eye and he did not discover until half an hour after he woke up that it was no longer present although up to that time he said that the least light caused extreme discomfort and spasm of the eyelid After the third treatment he found that he could see almost as well with his left eye as before he was hit on the head. Meanwhile he was still unable to walk without crutches although the wound in the leg had completely healed, and there was no physical cause to account for this When he was hypnotised for the fourth time it was therefore suggested to him that he would be able to walk quite well, and he subsequently recovered entirely

These cases are typical of many others that have been treated similarly, in fact, fresh cases of this same condition are arriving every week and the "suggestion" treatment has not failed to give marked improvement in every instance Up to the present we have had no failures, although the patient in Case 5 has proved the most resistant, but his deafness and domestic trouble, together with the very unfortunate handling of the case in the early stages, have no doubt been responsible for this Mr Francis Brook very kindly undertook the later stages of his treatment for me (A W O), as owing to his greater experience in this work I thought he might obtain better results than I had effected In November the patient was given an anæsthetic, and suggestion was tried during the stage of semi consciousness with marked success as on the following day he opened his eyes voluntarily and has kept them open ever since His speech and his sight having now returned, we hope that his hearing will not be long delayed

Dr Hertz and I trust that by publishing these cases greater attention may be drawn to these conditions, so that even if treatment cannot be applied at once the cases may not be prejudiced unfavourably by injudicious handling

It is probable that the presence of sand grit, &c., in the conjunctival sacs of some of these patients may have been the cause of the "suggestion" of blindness but it was not present in all cases and recovery took place without its being removed as a matter of fact they were when present, all embedded in the conjunctiva and did not produce any irritative symptoms at the time the patients were under treatment

A NOTE ON WIDAL'S REACTION WITH STANDARDISED AGGLUTINABLE CULTURES,

TOGETHER WITH REMARKS ON THE IMPORTANCE OF METHOD IN RELATION TO AGGLUTINATION TESTS

BY E W AINLEY WALKER, D.M. OXON,
FELLOW AND TUTOR OF UNIVERSITY COLLEGE, AND LECTURER IN PATHOLOGY IN THE UNIVERSITY OF OXFORD

(*From the Department of Pathology, University of Oxford*)

IT will be generally agreed that at the present time, when large numbers of cases of febrile intestinal disorder are being admitted to military hospitals in this country and elsewhere, the routine use of reliable, accurate, and rapid methods of bacteriological diagnosis is a matter of more than usual importance Particularly is this the case in relation to the application of agglutination tests in the diagnosis of typhoid and the paratyphoid fevers

The Microscopic Method

During the last ten years there has been a gradual consensus of opinion among those who have studied the subject in the greatest detail that macroscopic methods of carrying out the Widal reaction are both simpler and more reliable than the microscopic method. Nevertheless, the microscopic method still appears to possess somewhat numerous adherents in this country as a routine procedure And the opinion has been again put forward quite lately by Tidy[1] that microscopic and macroscopic methods are equally reliable for diagnostic work This is perhaps true in the sense, but only in the sense, that any method will enable the observer to report that agglutination did or did not occur in particular dilutions of the patient's serum Doubtless, also, if agglutination has been obtained by the microscopic method in a sufficiently high dilution of the serum in an *uninoculated* individual a *positive* diagnosis may be given with reasonable certainty

But that the percentage of correct results, positive and negative, obtained by microscopic methods approaches anywhere near the degree of accuracy obtainable by the best macroscopic methods of performing the test cannot be substantiated by evidence Indeed so numerous are the irregularities and the pitfalls in the agglutination test as carried out under the microscope, and so greatly are its difficulties increased where *inoculated* individuals are concerned that the results are often practically valueless in diagnosis, and may even be entirely misleading

What are these difficulties and irregularities, and how do they arise? The position may be indicated broadly in the following manner Typhoid agglutinins for example, may be present in the blood in appreciable amounts for one of several reasons 1 The patient may have active typhoid fever 2 He may be convalescent from the active disease 3 He may have had typhoid fever in the past with persisting agglutinins 4 He may be a typhoid carrier with an agglutinating serum 5 He may be an inoculated individual Now any one of these conditions may be associated with pyrexia and undiagnosed intestinal disorder requiring the application of agglutination tests But in many cases the various conditions just enumerated are not distinguishable by Widal's reaction unless a method is used which allows one to determine whether, and if so how much, the titre of the patient's serum alters from day to day or at intervals of several days This, however, for reasons which will be explained immediately, is impossible by the microscopic method unless the changes in the titre are very great With appropriate modifications similar statements hold with reference to paratyphoid agglutinins

On the other hand, in cases and at stages when the titre of agglutination is low agglutination may not be detected by the microscopic method and the case returned as negative because the culture employed on that occasion happens to be one of relatively low sensitiveness to agglutination or the emulsion too dense When it is added that the precautions and controls against spontaneous agglutination may fail to be adequate in a proportion of cases abundant grounds are present to explain the conviction which at an earlier period in the war was being forced upon clinicians, and was expressed by Colonel Sir Bertrand Dawson[2] in quite definite terms to the effect that agglutination tests, *as performed, often failed* to afford reliable guidance in the diagnosis of typhoid and the paratyphoid fevers "owing to the failure of the Widal test due to inoculation" and to the fact that it was "eccentric," varied from positive to negative on successive days, and might be negative though typhoid bacilli were actually found in the blood Yet when carried out by accurate quantitative macroscopic methods agglutination offers far the simplest and most delicate test which we possess for the recognition of these particular infections

The reasons why the microscopic method entirely fails to give comparable quantitative measures of the titre of a patient's serum on successive occasions are the following

1 The bacterial emulsions or bouillon cultures employed are of an undetermined and inconstant bacterial content They possess no fixed and definite density, and are not twice alike Nor is it known to what extent they differ Yet it was shown long ago by Sacquépée[3] and is now familiar that the agglutinating power of one and the same serum will vary by *100 per cent* and more with the density or thinness of the emulsion used

2 Cultures vary very greatly in their degree of sensitiveness to agglutination so that different subcultures *derived from the same stock may differ* in sensitiveness to agglutination by *100 or 200 per cent*

3 As Bossaert[4] and others showed the precise age of the culture used affects in an important degree the sensitiveness of the culture to agglutination particularly in the case of bouillon cultures

4 Slight differences in the culture medium concerning the quality of the meat extract used in its preparation the precise chemical reaction of the finished product, the proportion of salts present and other factors may greatly affect the sensitiveness of the culture to agglutination

It follows that the microscopic method with fresh living cultures (the method cannot satisfactorily be made use of with killed cultures) is liable to variations of some hundreds per cent It cannot therefore indicate *with certainty* any changes in the agglutination titre of the patient's serum at successive examinations unless the changes are so very large as to fall outside the limits of these errors Within these limits such changes as appear to be indicated are as likely to be due to the inherent errors of the method as to any actual change in the titre of the serum while on the other hand the method may for the same reasons fail to reveal an alteration in agglutination titre even when a change of magnitude has taken place

Incidentally these facts explain how it is that while it has been clearly shown by quantitative macroscopic methods that in typhoid fever,[5] in inoculated persons,[6] and in inoculated experimental animals[7] the course of agglutination followed from day to day pursues a regular curve other observers using other methods find the trace composed only of a series of irregular jumps Of the fact that gross irregularities of this character are inherent in the microscopic method anyone may readily convince himself who will take the trouble to test one and the same known agglutinating serum by this procedure on a succession of different occasions

It is not intended for a moment to imply by what has here been said that the microscopic method will not in experienced hands give, earlier or later in the course of the disease, a correct answer, Yes or No, to the diagnostic question in a large proportion of straightforward cases, but will very often fail to afford the evidence required in the conditions of doubt laid down above

What is required in these cases is not a simple answer, Yes or No, but sufficient evidence on which to form a judgment whether the agglutination titre is rising, or falling, or maintains an approximately steady level during a period of observation Further the method used must be one which is not likely to fail whenever any special difficulty is encountered

The Macroscopic Method

The sedimentation method introduced by Almroth Wright[8] in 1897 constituted an important advance in the technique of the Widal reaction But Madsen[9] in 1902 was the first to devise a really accurate method of measuring the agglutinating power of immune serum It is not however always possible to make measurements by Madsen's method, nor is the method one so easily applicable in diagnostic work Madsen used bouillon cultures to which 1 5000 formol was added just before use During the succeeding years a number of observers advocated the use of cultures killed by formol and in various other ways for the performance of agglutination tests It is impossible in a short space to discuss in detail the various modifications of the macroscopic method But beyond question the best and most generally useful of these methods for accuracy, precision, simplicity and safety was that devised by Dreyer[10] published in 1906 after several years of careful trial and experimentation and made more generally known to English workers by translation in the *Journal of Pathology and Bacteriology* in 1909

In experimental work a long series of tubes is used in which the quantity of serum in each tube is approximately 80 per cent of that in the immediately preceding tube all the measurements being made by means of accurately calibrated pipettes For diagnostic work a short series of small tubes is used and the measurements are made with a dropping pipette Each tube is made to contain exactly the same quantity of killed agglutinable culture and exactly the same total volume of fluid

The accuracy of the method in the di[illegible] of enteric fever may [illegible] during the first two comp[illegible] the laboratory of the [illegible] (19[illegible] 1907) [illegible] 50 [illegible] was obtained in 99.1 per cent. of the cases which proved to be typhoid fever and a negative result was arrived at in 98.77 per cent. of the cases which proved not to be typhoid fever.[10]

As originally applied, two series of five tubes were used and the serum tested both against B. typhosus and B. paratyphosus (B). But present conditions are met by the use of three series of tubes in each stand, and the serum is tested simultaneously against B. typhosus and both the paratyphoid bacilli, as described in detail in the early part of this year.[6] A very thin emulsion of standardised opacity is used, thus getting rid of all the irregularities above referred to which are produced by the use of too dense emulsions and emulsions of varying and undetermined density. The reaction always proceeds in the same total quantity of fluid and in the presence of a constant quantum of bacteria. The killed agglutinable cultures are prepared from strains of bacteria specially selected and manipulated to ensure a high degree of sensitiveness to agglutination as well as to avoid spontaneous agglutination against which controls are put up with each agglutination test, though the phenomenon is practically never met with in the standardised cultures. Further, the degree of sensitiveness to agglutination—i.e., the agglutinability—of each batch of culture is accurately determined in terms of the original standard culture, and is expressed by means of a standardising factor.

The reading is taken by noting the highest dilution in which marked agglutination (without sedimentation) can be detected by the naked eye. This degree of agglutination is termed standard agglutination, and may very simply be expressed in standard agglutinin units by reference to the standardising factor of the particular standardised agglutinable culture employed.

Dreyer's method has now been tested for more than ten years, not only in experimental investigations but also in routine laboratory work and ordinary class teaching. It is not likely, therefore, that any important new difficulties will arise in its use in ordinary routine diagnostic work.

Since the early summer of this year standardised agglutinable cultures of B. typhosus, B. paratyphosus (A), and B. paratyphosus (B), and standard agglutinating serums for these micro-organisms have been made widely available by the Medical Research Committee on whose behalf they are issued (with directions for use and diagnostic data). Not the least benefit which will accrue from this action will be the collection from many parts of the world of an extensive material of exact and comparable data. For the individual worker the use of these preparations offers the following advantages:—

1. They are absolutely sterile and require no expert knowledge in handling.
2. They are always ready, there is no making of cultures in advance or preparing of emulsions.
3. The method is extremely simple, so that if need be an intelligent attendant can easily be taught to set up the tests.
4. The readings are quite clear and definite and quickly made.
5. The standardised agglutinable cultures are highly sensitive to agglutination and they can be kept unchanged for a year or longer.

The employment of an accurate quantitative method of carrying out agglutination tests possesses special value in the diagnosis of the presence or absence of active typhoid or paratyphoid infection in (typhoid) inoculated persons. If, and wherever, a mixed inoculation is brought into use it will become essential to use some such method in order to distinguish the persisting inoculation titre of the serum from the titre of active infection, since in inoculated individuals the agglutination curve of active infection is *superposed* on the agglutination curve of past inoculation. By the time infection takes place the latter will probably have reached a stage of decline in which it has become to all intents and purposes a level line in observations made at a few days' interval, so that in reality the agglutination curve of active infection starts in these cases from a raised base line. Recently, however, statements are reported to have been given currency by Tidy[1] to the effect that "febrile conditions apparently removed the agglutinins to bacillus typhosus from the blood", that "a positive Widal reaction was equally valuable in the case of the inoculated and the uninoculated", and that "after having disappeared the agglutinins perhaps return, but this is not usual." All this would naturally lead to the conclusion that if typhoid agglutinins be found in the blood during or subsequently to some still undiagnosed febrile affection their presence is to be attributed to active typhoid infection. This is not at all the case. But it is to be feared that if the view in question were to gain general acceptation a very large number of the typhoid inoculated individuals who developed a febrile disturbance would if examined be returned as cases of typhoid fever. Such a statement, therefore, justifies a definite contradiction. The effect of paratyphoid infection, for example, on the typhoid agglutinins of inoculated individuals, examined at such time as they are admitted to hospital, is either to leave the typhoid titre *unchanged*, or to produce a *rise* of greater or less degree.[6] And this agrees with what has been familiar in animals for a number of years.[7] Thus if an animal which has been immunised some weeks or a month or two before with *a particular* micro-organism be inoculated with a non-lethal dose of a vaccine prepared from some other micro-organism its agglutination titre for the first micro-organism exhibits a new rapid rise of greater or less extent and pursues a curve similar to the ordinary inoculation curve.

Immediately upon the second inoculation there may occur in a proportion of cases a moderate and purely temporary fall in titre, probably somewhat similar in character to the negative phase of the opsonic index, and passing off within a day or two to be followed by the rapid rise just mentioned. But if a longer period has elapsed (e.g., five months or more) before the heterologous inoculation is given there may be no change of any kind in the agglutination titre, though whenever any change at all does actually occur its main *feature* is a rise in titre.

AN OUTBREAK OF ANTHRAX CONVEYED BY INFECTED SHAVING BRUSHES

BY REGINALD R ELWORTHY, M D LOND, M R C P LOND, D.P H CAMB,
PATHOLOGIST TO THE WEST LONDON HOSPITAL

THE following examples of anthrax in man are worthy of publication inasmuch as they seem to be the first recorded instances of such a means of contracting the disease Of the three cases that were definitely proved to be caused by the use of infected brushes, two—referred to later as the D—— and B—— cases respectively—survived the disease, whereas the other (the W—— P—— case) proved fatal As the fatal case was the one that suggested this mode of contracting anthrax, and also provided other features of interest during life, its details are here described at some length This paper, then, deals with (1) three cases of anthrax proved indubitably to have arisen after the use of a fully manufactured but still infected article, and (2) the bacteriology of (*a*) certain unused brushes manufactured at the same period, and (*b*) the materials used in their composition I do not deal with the means adopted to control the distribution of such brushes as could be traced to the infected consignments except to say that, on the facts becoming known, prompt action was taken to secure, so far as possible, their withdrawal

Clinical Notes of the W—— P—— Case

The patient was 32 years of age June 29th In the evening he noticed what he considered to be a boil coming on the front of his neck 30th He woke up to find considerable swelling of his neck His medical attendant noted a high temperature and much œdema of the neck but no "pustule" formation July 1st He was admitted to the West London Hospital

Condition on admission —There was a small yellow patch of subcuticular necrosis over the most prominent part of his thyroid cartilage in the middle line, with about half a dozen vesicles lying on its margin and extensive œdema limited above by the lower jaw spreading over the clavicle below, and fading gradually towards the middle line behind The mass was tender on manipulation and non crepitant Temperature, 99° F , pulse rate, 120

After a general anæsthetic at 7 P M the patient became conscious but remained profoundly collapsed throughout the night, sweating profusely and becoming gradually more cyanosed The temperature was subnormal, and the pulse-rate 150 and over Death occurred at 7 30 A M on July 2nd the total duration of illness being 60 hours No bacteriological examination was made during life

At the post-mortem examination held six and a half hours later it was seen that the œdema had made considerable headway extending from the lower face above to the xiphisternal notch below Laterally the outline of the neck was so deformed that the natural break between head and shoulders was almost obliterated giving from in front a frog like appearance Over the pomum there was a surgical wound half an inch long and one-eighth of an inch broad Dissection at this spot showed very little if any destruction of tissue apart from the surgical incision Preliminary punctures withdrew yellow slightly turbid odourless fluid from the front of the neck and a similar but sanious exudate from the parts affected by hypostasis Hangdrop and smear preparations made from this fluid showed few leucocytes but numerous large non sporing non motile encapsulated bacilli The same bacillus was subsequently seen to occur in great numbers in smears from the blood spleen kidneys lungs and exudates The other appearances noted were an œdematous infiltration of the anterior middle and posterior mediastina with a large serous collection in the left pleural sac hypostatic congestion of the lungs, staining of the endocardium and the intimal lining of the vessels dark and mainly fluid blood , heart muscle atonic , peculiar dry, ground glass appearance of the peritoneum, with collapse of the g[illegible] injection of the stomach and intestine with scattered small hæmorrhagic erosions and a little altered blood in the former , a small but dark coloured spleen (6 [illegible]) and no obvious enlargement of the glands The brain was not examined Positive cultures possessing the cultural and biological characteristics of B anthracis were obtained from the spleen, lungs liver, stomach, and upper intestine, and œdema fluid from the neck mediastinum and pleura, but not from the bronchial mucus There was no urine to examine Control anaerobic cultures from the neck blood, and spleen showed no bacterial growth It was concluded that the bacillus had entered the blood stream through the skin of the neck, as no appearance of a primary lesion in the intestines or the lungs could be discovered

Clinically this was an example of so called "erysipelatoid" anthrax, which is characterised by the insignificance or deferred appearance of "pustule" formation, rapidly spreading œdema and a high mortality It is usually seen in the neck or eyelids where the tissue is loose and cellular In such tissue there is probably little power of resistance to invasion and no barrier formed to prevent early bacteriæmia However the œdematous infiltration may be marked without death ensuing There is an example recorded in the Annual Report of the Chief Inspector of Factories for 1908 in which a flesher, who had extensive œdema of the face, upper extremities, trunk, and right thigh recovered after the use of 90 c c of Sclavo s serum in 20 c c doses [1]

An early diagnosis was rendered difficult partly on account of the type assumed by a disease which is rarely seen in most London hospitals but chiefly because the man s occupation was one of the last to suggest anthrax The odds were as much against his having a cellulitis of the neck due to B anthracis as they would have been in favour of this had he been a brushmaker or hide salter

Having proved the identity of the bacillus by culture and inoculation, the point of immediate interest to decide was in what manner infection came about With this object in view, and bearing in mind the protean nature of anthrax purveyance some of the patient s relatives were rigorously questioned, but with so little success at first that it seemed that this case would have to be relegated to the unsatisfactory group of unproven etiology were it not for an observation made at the post mortem examination At that examination it was noted that the small local lesion came well within this individual s shaving area which covered a larger ground than usual This suggested the idea that a new shaving brush might have laid a charge which the subsequent passage of a razor exploded This was thought of not so much because the lesion was on the neck—a site very commonly infected in workers in all the scheduled industries—but because it occurred in the shaving area and moreover, in a part supported by the hard thyroid cartilage, where the attrition of the brush might deposit most spores and the razor edge could easily wound The relatives of the patient were therefore asked to follow up this clue with the result that another member of the family the actual purchaser and donor of the shaving brush stated that her son had certainly used the brush she had bought during the fortnight it had been in his possession but only a few times as he had not altogether discarded his old one

At the subsequent inquest a verdict was brought in that death was due to anthracæmia possibly contracted from shaving with an infected brush At this inquiry expert veterinary opinion was opposed to this provisional suggestion. It was held that vegetable fibre rather than animal was usually employed in the making of these cheaper brushes, and that infection from them was therefore improbable But the three facts—viz , the site of the lesion, the use of a new shaving brush, and the absence of any other discoverable source of infection, together with the one possibility, viz , that the fibre used in that new brush might be of animal origin and infected—were sufficient to suggest a working hypothesis which later investigation proved conclusively The idea was considered chimerical in certain quarters, probably because it was without actual precedent In others it seems to have caused annoyance, and it must be confessed that the supposition was put forward with a reserve that would not have been present if the brush had been examined before the inquest

---

[1] In the W—— P—— case [illegible]

About a week later the brush was available for examination Fortunately it had not been washed after the last time of shaving, an important accident as will be seen later It was of poor quality (wholesale price 6*d*) The fibre used was animal with a small leaven of vegetable The former moiety appeared to be made up of hair of various kinds, some being artificially dyed to resemble badger After comparison with known samples, it was concluded that pig bristles, horse hair, and possibly cow tail were present, but owing to lack of experience in this intricate differentiation an exact classification could not be formulated The main point, however, was that animal hair was present in abundance, which showed that the assertion made at the inquest that cheap brushes were mostly composed of vegetable fibre did not apply to this sample The other constituents were the bone handle and the cementing substance, the latter of which might or might not have been of animal origin In the bacteriological examination the bone, the cement substance, and the hair were treated separately Several fragments of cement material obtained as far away as possible from the hair and scrapings from the surface of the bone handle were proved to be free from B anthracis by cultural methods, and for the moment no more time was spent over their examination

As regards the examination of the hair a rather ambitious and perhaps over cautious programme was arranged It was thought that if a wash made from all of them was inoculated into an animal death might ensue from some infection that would mask anthrax It was also thought that the infection might be limited to one variety of hair in particular Therefore about a third of the fibre was removed from the handle This freed portion, after a prolonged scrutiny, was divided up according to the varieties of hair it was thought were present—i e , those elements considered to have been derived from pig horse or cow were separated into groups and the unrecognised remainder treated as a separate batch These hairs as arranged, were then examined (*a*) singly by heating in broth at 80 C for 30 seconds and laying in parallel rows on surface agar and (*b*) in groups by washing in broth and plating the centrifuged deposit after heating Inoculation direct from the washings was not performed in these preliminary experiments which were fruitless only one organism being found on the plates which appeared to merit a trial by injection Rather a long time was wasted over these endeavours to allocate the spores to particular hairs and in the light of present knowledge the attempts were not worth the labour involved, as the original classification of the hairs was probably inaccurate Moreover, the fact that the brush had already been wetted during shaving with the likelihood of a universal distribution of the spores was at that time overlooked But mention is made of the work, as the time spent on it caused delay in the successful attainment of the object aimed at

Later the rest of the brush was "lathered" in a stone mortar in imitation of the ordinary process occurring in shaving with 20 to 25 c c of sterile broth rendered definitely alkaline to phenol phthalein with 5 per cent sodium hydrate The collected washings, after heating at 80° C for 15 minutes, were divided into three portions One of these was stored for further work if necessary The second was centrifuged and the deposit collected in 1 c c of the supernatant broth. This was thoroughly shaken and distributed in decreasing amounts through three agar plates Among the many colonies which occurred on these plates three proved to be B anthracis on subculture and inoculation The deposit from the remaining third was injected into a young rabbit weighing 1000 grammes This animal died three days later from typical anthrax, but in order to be correct academically the organism grown from the animal s blood was subcultured and inoculated into a guinea pig with similar results

It could now be definitely stated that the shaving brush was infected with anthrax This infection was probably due to disease in the animals from which the hair used in their manufacture was originally obtained It might however, be urged that it was brought about by contact with an abraded anthrax lesion This point could only be settled by an examination of unused brushes These brushes, five in number, together with the one bought and used by the patient in the W—— P—— case, comprised a lot of six from the same manufacturer exposed for sale in a druggist's shop They were dealt with in the same way as the original brush—i.e , by "lathering" in alkaline broth and treating the washes in the manner already described These washings were invariably very dirty Great care was exercised in rinsing and sterilising each mortar before treating another brush, as it was thought that otherwise infection might easily be carried through a series of brushes In the plates importance was only attached to the deep colonies, as described by Professor Eurich in the *Journal of Pathology and Bacteriology* vol xvi , 1912

Results Obtained from the Examination of Brushes

Brushes	Result of inoculation into guinea pig	Growth on agar plates
No 1[*]	B anthracis	A few colonies of B anthracis
2	Negative	—
3[†]	B anthracis also B perfringens	Many colonies
4	B anthracis also B malignant oedema.	Many colonies
5	B anthracis	Not done.
6	B anthracis	A few colonies
1a	B anthracis also B perfringens.	Many colonies
2a	B anthracis	Not done
3a	B anthracis also B perfringens.	Many colonies

[*] Original brush

[†] After the first inoculation a further attempt to find the spores of B anthracis in the wash from this brush was not made

The foregoing list of results obtained from the examination of two batches of brushes—the first six being those obtained from the druggist s shop—shows the widespread distribution of the spores and how gross the infection was on certain of the brushes Plates were not made from all the deposits on account of pressure of work

The animals inoculated survived periods varying from 30 hours to 5 days Those that died soon—viz, those inoculated from Brushes 3 and 4 and 1 A and 3 A—did not show the characteristic post mortem appearances of anthrax, but there was no difficulty in obtaining the bacillus by culture from the blood and spleen It was also noted that one of the dust organisms occurring on the plates occasionally contaminated B anthracis in cultures from the blood and spleen, but this organism did not seem to be pathogenic when inoculated by itself

After the above series was completed, a brush from the same manufacturer, which had been used in the D—— case by a man who had contracted facial anthrax, was tested It was found on arrival to have been well cleansed, judging by the complete absence of residual soapsuds and particles of beard, much of which still adhered to the brush from the original case The bacillus was not obtained from the free portions of hair even after repeated trial This failure may have been due to the fact that all spores had been removed during shaving and when the brush was washed after shaving To strengthen the supposition that thorough washing would free these brushes from infection, the following tests were applied —

1 Brushes 3 and 4 and 1 A and 3 A from the above batch were well rinsed in warm water from a running tap They were then dried and treated in the same way as in their first examination The centrifuged deposits obtained from the second washes were combined and inoculated into one guinea pig with negative results Plates were also made and they showed a very great diminution in the total number of organisms

2 Some of the "goat hair" mentioned hereafter, was well washed in hot soap and water, and then rinsed in hot running water After this procedure the deposits obtained from a further washing in a small quantity of alkaline broth failed to infect after inoculation It might be added that though the washing of hair fixed to a handle did no damage to that hair but apparently freed it from a potential danger, the same process applied to untethered hair resulted in such inextricable confusion that it became useless for brush making Moreover, the spores were not destroyed but only displaced by this method

The brush from the D—— case was at last proved to be infected when the ends of the hair imprisoned in the handle were examined After freeing them from the cement substance, as much care as possible being used, it was noted that they were markedly damaged by heat However the animal inoculated with the greater part (three quarters) of the deposit from their washings after heating at 80 C for ten minutes died eight days later from anthrax On the other hand a plate made from the remaining quarter of the deposit did not show a single organism of any kind

The next material to be examined were samples of Chinese goat hair and hog bristles, which were said to have been mixed and used in the composition of these brushes A sample of dust from the wooden bin in which the bundles of goat hair were stored was also collected at the same time Of these, the hog bristles were well bleac and clean in appearance Anthrax spores w neither found in them nor in the dust—alt negligible in amount—that had been scraped f the bin The "goat hair was dirty and washi from it gave a muddy deposit

A variety of animals seem to have contribut share in the constitution of these bundles of hair " Occasionally vegetable fibres were found

Plates made from the washings and gr aerobically teemed with colonies about half which were those of B anthracis The ani inoculated died in 30 hours from emphysemat gangrene caused by a very mixed infection, cultures from the spleen and blood gave n anthrax colonies Before these were secure piece of the agar plate containing two colonie anthrax was broken up and injected into a sec pig, which succumbed in three days and show anthrax only It is remarkable that no cases anthrax occurred amongst the hands employe the factory

With a view to an explanation of the occurre of so large a number of spores in the mater worked with, tests were now done to detect presence of blood and protein on these hairs and the washings obtained from them But neit was found in amounts sufficient to assume soil with animal tissues or discharges The benzi test gave an indefinite reaction, which was not c firmed by the other "occult blood tests Pro bodies could also be considered absent from practical point of view

The following observation, though very insu ciently worked out, may be mentioned as throw perhaps a little light on hair infection

About 30 pediculi found in a guinea pig de from anthrax were planted out on to the surf of agar plates, without any preliminary heating destroy other organisms Two gave rise to colon of anthrax, which appeared first about the m regions of the pediculi (Of these two colonies o was confirmed by inoculation and the ot identified by culture only) But one or t attempts to prove that hairs cut off from part the same guinea pig well away from the extern orifices were infected were made without succe

The finding of the two anthrax carriers mig have been due to good fortune, and many mo parasites might have been examined without di covering further infection If allowance is ma for the greater size of the parasites preying o larger animals the greater is the possibilit of hairs of these animals becoming infected by t excretions of such parasites

These and other experiments with the flies livi in the animal room were not pursued fur owing to exigency of time and the change season It is probable that animal inoculati would be a better means of detecting infection such insects than a plating out method which alone used in the few experiments carried out

The last two brushes to be investigated w associated with a case that occurred in I—— T patient was a young adult aged 20 who devel a malignant pustule on the back of the nec T two brushes were even of a commoner kind t the ones previously spoken of The whole price was 3d This youth had bought h about six weeks before his illness but hi suggests that he did not have to use it of the time The second brush was ob as a control from the store which the been bought It was of the same pattern The results of the examination were as follows —

Brush	—	Guinea pig	Plates
No 1	Used	B anthracis Guinea pig died on sixth day	Not made
No 2	Unused	Died from emphysematous gangrene	Not made

These results were not in accordance with anticipation It was thought that as the lesion was on the back of the neck the shaving brush would probably be found blameless So it must be concluded that infection was caused by the fingers or a face cloth, either of which might readily become infected

Interest attaches to the result obtained by another bacteriologist, which showed the presence of anthrax infection in a sample of the material said to have been used in the manufacture of the brush in question

West London Hospital

THE DIAGNOSIS OF SO-CALLED PRIMARY TUBERCULOUS MENINGITIS

RETENTION OF URINE IN THE ADULT MALE, WITHOUT ANY APPARENT CAUSE, AS A NEW PATHOGNOMONIC SIGN[1]

By D W KEILLER MOODY, M D ABERD,

SURGEON (TEMPORARY) ROYAL NAVY

TUBERCULOUS meningitis in a child is a disease which can generally be easily diagnosed, but in the adult, unless there is distinct evidence of tuberculous disease elsewhere, it is very difficult and in many cases impossible, to do so Comparatively recently I have come across four cases of this disease in the adult (male) in which there was retention of urine without any apparent cause, and I have in consequence come to look upon it as a pathognomonic sign The act of urination is a voluntary one, a sensory stimulus is sent from the bladder to the brain, which is possibly a sensation of distension of the bladder The response to this is a voluntary act—contraction of the abdominal muscles This presses a few drops of urine into the sensory neck of the bladder which gives rise to the spinal reflex which produces contraction of the bladder walls with inhibition of the sphincter at the neck of the bladder, and so urination In the cases I have written on there was no paralysis of the abdominal muscles and no pain or desire to micturate Evidently sensation was absent, but why I cannot explain

CASE 1 —Male aged 20 years shop assistant Had not been feeling fit for some time Fairly well nourished Complained of headache No sickness Temperature 101° F Pulse rapid, tongue dry no cough No cyanosis flushed appearance Respirations normal Bowels constipated Heart both sounds present, no adventitious sounds Lungs normal No enlargement of spleen or liver Urine specific gravity 1020 amber coloured acid, no albumin or sugar Bowels moved by enema yellowish no blood During the next five days temperature was irregular being normal in the morning and varying in the evening from 101° to 102·6° On the morning of the sixth day he told me he had not passed urine since the day before The bladder was distended I passed a rubber Jacques catheter quite easily Urine tested again normal No paralysis of abdominal muscles I could not come to a [illegible] opinion [illegible] still no diagnosis [illegible] became irregular and slow Respirations more frequent Pupils dilated and irregular Gradually sank into a semi conscious condition Coma developed later and he died on the tenth day Towards the end the temperature became normal I had to draw off urine every day until he died

Necropsy —A post-mortem examination was performed (at which a pathologist was present) Brain Matting together of the membranes, effusion of lymph, which was opaque, round base of the brain, especially round the optic chiasma and in Sylvian fissures, several whitish nodules on various parts of the brain, very few and very difficult to find There were no tubercles mixed with lymph Miliary tubercles were found in various organs liver kidneys, &c Otherwise all the organs normal The prostate was not enlarged Death was due to tuberculous meningitis secondary to acute miliary tuberculosis

What struck me most about this case was that the patient was unable to pass urine He had no pain although the bladder was distended and he had no desire to pass urine There was no stricture or enlarged prostate He simply mentioned the fact that he had not urinated, as it struck him as being "rather funny" Evidently sensation was quite absent and there was no paralysis of abdominal muscles

CASE 2 —A male, labourer aged 35 years, who had been to all accounts, in good health previously, was suddenly taken ill one evening I saw him the next morning, he was then in a comatose condition Very cyanosed, temperature normal, tongue dry Pupils widely dilated and irregular Pulse slow feeble, and irregular Heart, both sounds present, no adventitious sounds Lungs normal Liver and spleen not enlarged Bladder dull note nearly up to umbilicus, passed Jacques rubber catheter quite easily The urine was of specific gravity 1015, cloudy, acid no albumin or sugar Typical Cheyne Stokes breathing Incontinence of fæces He died the same evening The temperature was still normal

Necropsy —At the post-mortem examination there was matting together of membranes of the brain and a large quantity of turbid lymph mixed with tubercle at the base surrounding the nerves and extending into the Sylvian fissure There was a large patch on the anterior portion of the convex surface of the cerebrum The ventricles were full of fluid, other organs in the body were normal The prostate was not enlarged Death was due to tuberculous meningitis I could not find any primary cause although there was probably a caseous gland somewhere When I discovered that the bladder was full I at once thought of Case 1 and that this also might be another case of so-called primary tuberculous meningitis, and so it proved

CASE 3 —The patient a male aged 31 years whom I saw in the evening had been "seedy" for some time and was now in a drowsy condition He understood what I said to him but before I could get a reply to my question he would relapse into the same drowsy state The temperature was normal and the pulse slow feeble, and irregular The patient's mouth was full of blood evidently from biting his tongue, nothing in the throat, very cyanosed, dyspnœa Both heart sounds were present, no murmurs The lungs were normal there was slight cough but no sputum Liver and spleen dullness normal The bladder was distended, a Jacques rubber catheter passed easily Urine Specific gravity 1010 cloudy alkaline no albumin or sugar There was a large quantity of earthy phosphates which probably accounted for the alkalinity No paralysis of the abdominal muscles The patient being constipated an enema was given, the stools were quite black probably due to blood swallowed Kernig's sign was present also tache cérébrale He rapidly became worse, the respirations increased and the pupils were widely dilated and irregular He sank into a deep coma and died the following evening

Necropsy —At the post mortem examination the brain showed all signs of tuberculous meningitis Both kidneys were cystic and weighed 2¼ and 2¾ oz respectively The prostate was not enlarged other organs normal I could not find any primary cause but I did no search very minutely After the experience of the first two cases the moment I found the bladder full I felt perfectly certain in my own mind as to the diagnosis and what I should find post mortem, and the result proved my expectation to be correct

---

[1] [illegible] Moral [illegible] General P[illegible]

The following case tends to confirm the observations recorded in the first three cases —

CASE 4 —The patient was a male aged 47 years When I first saw him he was in a very weak condition suffering from advanced tuberculous disease of both lungs The pulse was irregular and slow He was very cyanosed and was constipated On the third morning the nurse informed me that he had not passed urine The bladder was distended, I passed a Jacques rubber catheter quite easily The urine was high coloured, of specific gravity 1025, acid, with no albumin or sugar There was no paralysis of the abdominal muscles and no enlarged prostate Kernig's sign was present, also tache cérébrale That evening he had a more or less typical Jacksonian fit These fits continued with intervals until he died the following evening Respirations increased, temperature normal every morning The first day I saw him his evening temperature was 99° F On the following evening it was 99 2°, on the next evening 100° and on the night on which he died 103 6° His death was due to tuberculous meningitis, secondary to tuberculous disease of the lungs

Necropsy —I only examined the brain and found the usual tuberculous signs which one would expect

Case 4 is especially interesting, as there was ample evidence of tuberculous disease elsewhere, and therefore no doubt about the diagnosis The retention of urine was present without any cause, and the patient himself did not mention the fact that he had not urinated and seemed to have no pain or discomfort in consequence The diagnosis can nearly always be clinched by lumbar puncture, but this is a procedure which is often inadvisable or inexpedient

The laity always want to know what is wrong with the patient, but they do not always appreciate the difficulties that beset the physician s path I hope, therefore, that this sign of retention of urine, which, I think one is justified in calling "pathognomonic," will help in forming a diagnosis in those difficult cases of so called primary tuberculous meningitis I have searched the literature on the subject, but I have not read of this sign being quoted before It would be interesting to hear what the leading physicians have to say

A FATAL CASE OF "DOPE POISONING"

BY W E LEE, M D LOND, F R C S ENG

CASES of "dope poisoning" are so recent in origin and so few in number that it is desirable to make the record of each one as complete as possible The one here recorded is the fifth fatal case, and occurred at a large aeroplane works at Kingston

The patient a male aged 60, a "tapist,' went to Mr Isaac Coalbank, of Teddington on Nov 19th 1915 complaining of diarrhœa vomiting, and weakness which was so great that he could hardly walk a distance of less than half a mile to the surgery He was sent to bed and stayed there until his death on Dec 2nd The diarrhœa continued the vomiting altered in character becoming less frequent and a very much larger amount coming up at each time Jaundice came on three days later—i e on Nov 22nd—it became more intense and continued throughout the illness Petechial hæmorrhages appeared and increased in number until the body was covered almost as with a measles rash He became somnolent and this deepened into coma in which he died

Necropsy —A post mortem examination was made on Dec 3rd by Mr L A Clarke of Teddington at which Dr T M Legge of the Home Office Mr Coalbank Mr H Davidson Dr E G Gibbs-Smith medical officer of health of the district and myself were present Externally the body was well nourished with ample subcutaneous fat There was general jaundice of moderate intensity slightly paler on the legs than elsewhere On opening the abdomen the liver was not seen until the overlying stomach and intestine had been lifted up There was a large amount of free bile stained fluid The gall bladder was large, had many adhesions round it but contained no gall stones and none were found in the ducts The liver weighed 39 oz, its surface was wrinkled and it lost its shape when laid on the table The capsule was obviously too large for the contents The right lobe was almost normal in size and the left very small The right lobe was stained a bluish green colour, quite unlike that seen in post-mortem decomposition The left lobe was bright yellow On section very little blood escaped It was hard to cut firm to the touch, and the lobules very prominent The kidneys were large the capsule stripped readily the cortex was very narrow, and the pyramids were swollen The spleen was shrunken, congested, and friable The heart weighed 15 oz, the whole endocardium was smooth, deeply stained a dark red tint in uneven patches The heart muscle was similarly stained for a quarter of an inch below the endocardium and friable The stomach and intestines were normal The lungs showed some emphysema The aorta was stained in a similar way to the heart

Past history —The patient had been in the Royal Navy for many years, taking part in the West African and other expeditions He had then been a painter until Oct 23rd, 1915 when he started work in an aeroplane factory

The following points are of interest The taping room where the man worked is not regarded as being so dangerous as the painting room, where the whole fabric is painted with 'dope' in six coats, 24 hours being allowed to elapse between each coating Taping is putting on strips of fabric 2 inches wide over the fabric seams after dipping them in "dope" There is a good deal of vapour in the taping room, but not so much as in the painting room

The composition of the "dope" is important, it consists of acetate of cellulose or celluloid dissolved in tetrachlorethane, with amyl alcohol and benzene

The treatment of the case was tartrates, citrates and alkalies, with saline injections, plenty of water to drink, and stomach lavage

"Dope poisoning" is a new disease The first case occurred in November, 1914 and there have been three other fatal cases besides the one reported here A very full account of the first outbreak was published in THE LANCET of March 13th 1915, by Dr W H Willcox with an account of the microscopical appearance of the tissues The small size of the left lobe of the liver has been noted in other cases and seems to be characteristic of the disease An outbreak occurred in February, when several girls were the subjects, fortunately they all recovered The first fatal case was in a male the next three in women, and the one now recorded in a male The average age of the fatal cases is much greater than the average age of the cases which have recovered The disease is now a notifiable industrial disease under the Disease Section of the Workmen's Compensation Act

An action was brought by the widow of the first victim claiming that her husband had died as the result of an accident This was decided against her and the Aircraft Company paid her a sum of £150 on condition that she did not appeal against the decision

In conclusion I have to express my hearty thanks to Mr Coalbank for his kindness in supplying me with the clinical history of the case and allowing me to publish it

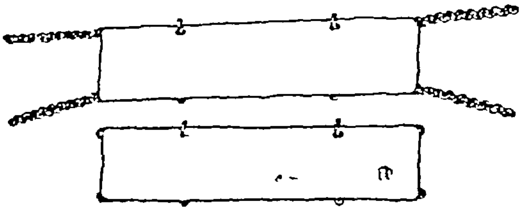
[illegible] E C

AN INTERRUPTED HAMMOCK-BED IN THE TREATMENT OF COMPOUND FRACTURES OF THE HIP AND THIGH

BY C W G BRYAN, F R C S ENG,
SURGICAL REGISTRAR ST MARY'S HOSPITAL, LONDON TEMPORARY CAPTAIN ROYAL ARMY MEDICAL CORPS

IN the treatment of septic gunshot wounds, especially where bones and joints are involved, it is recognised that two principles are of the greatest importance—namely, frequent change of dressings and immobilisation Immobilisation is necessary, not only to avoid pain and consequent exhaustion, but also to prevent auto inoculation from disturbance of the septic area Unfortunately, the more often a wound is dressed the more it is apt to be disturbed

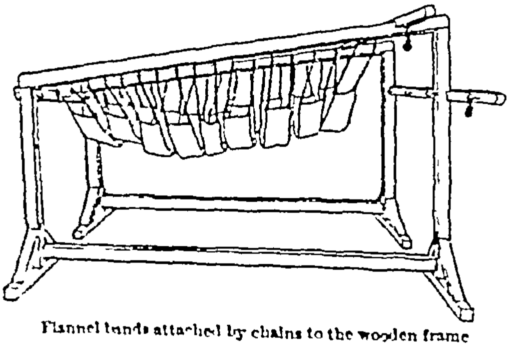
FIG 1



Four fold flannel bands with rings at the corners and hooks and eyes at the sides.

For the treatment of compound fractures of the upper extremity much ingenuity in devising splints has been displayed successfully, and forms of apparatus are available to enable nearly every type of wound to be dressed without disturbance In the lower limb, however, dressing without altering the position of the patient or his fracture may be a matter of very great difficulty, and especially is this the case when the hip joint or the upper end of one or both femurs is injured In these cases also there is usually a wound situated posteriorly, whether due to the projectile or to an operation for counter drainage

FIG 2



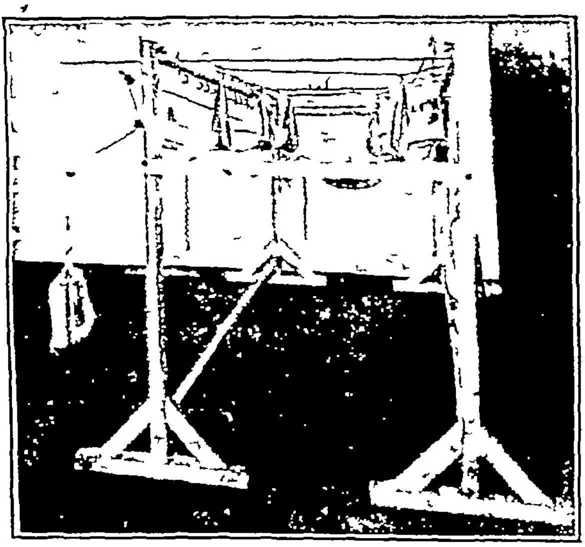
Flannel bands attached by chains to the wooden frame

Again the care of the patient s back, a particularly serious matter in these cases owing to wasting and the profuse discharge from the wound, and the other necessary manipulations of nursing lead to frequent disturbance of the patient In many cases he can lift his own body off the bed by pulling with his arms but this leads to an objectionable waste of strength when he is weak and toxæmic

Recently having to treat two patients with severely septic compound fractures of the femur involving the hip joint one of the wounds in each case being very large and placed posteriorly, I was led to devise a simple interrupted hammock bed in which the patient can lie practically undisturbed while all the processes of dressing and nursing are carried on

The bed is made with two ordinary Balkan splints which are united by three transverse cross pieces of wood so that their inner borders are 36 inches apart One cross piece is screwed to the head end vertical bars of the splints 40 inches from the ground, the second one is bolted to the foot end vertical bars of the splints, also 40 inches from the ground, and the third cross piece is bolted to the two overhead bars of the splints 12 inches from their foot ends The second and third transverse bars are prolonged beyond the Balkan splint on one side for 18 inches, so that full abduction by weight extension, which is usually necessary for fractures in the neighbourhood of the hip, can be obtained The fact that these bars are attached by bolts enables them to be reversed when necessary To the under aspect of the upper bars of the Balkan splints strong hooks are screwed at intervals of 4 inches To each of these hooks a piece of chain 10 inches long is attached

FIG 3



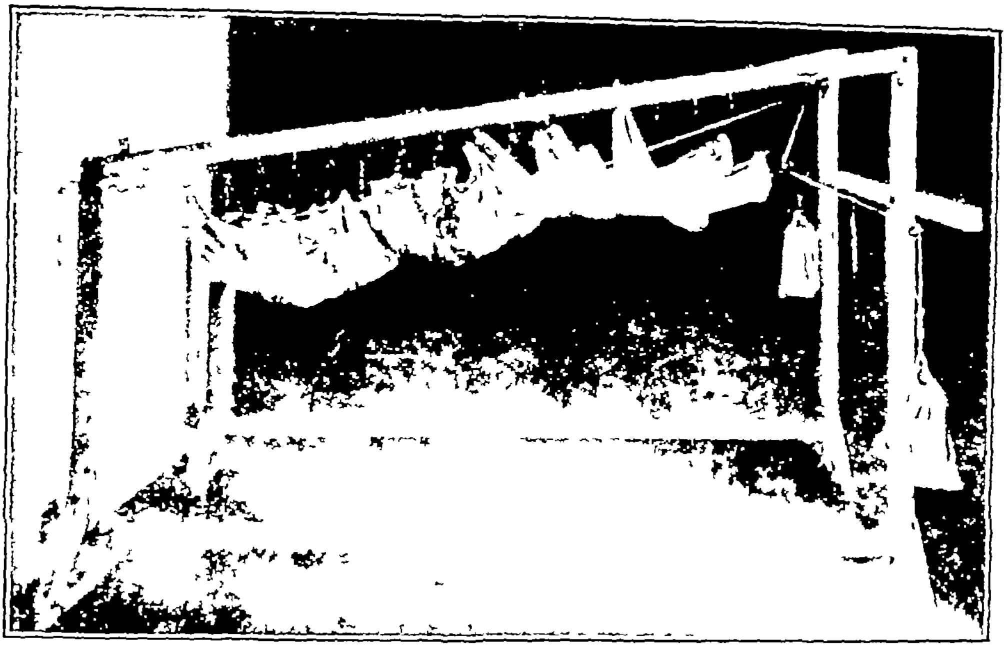
End view of bed in use by a patient with septic compound fracture of neck of right femur suppurative arthritis of right hip and septic compound fracture of shaft of left femur

The bed on which the patient lies consists of transverse bands of flannel Each band is made of four thicknesses of flannel, 36 inches long and 8 inches wide, and has sewn in each corner a small curtain ring, while to each edge, 9 inches from the end, large hooks and eyes are sewn (Fig 1)

Each corner of the flannel bands is hooked to the end of one of the chains mentioned above, and each band is attached to its neighbours by the hooks and eyes When the patient is in the bed the bands are adjusted so as to distribute his weight evenly by hooking the chains to the Balkan splints at a convenient link In some cases it is desirable to make the bands which are in contact with the dressings of rubber sheeting instead of flannel (Fig 2)

To immobilise the fractured limb I use two stirrups of strapping, one attached to the thigh, the other to the leg From the upper stirrup a cord

FIG. 4



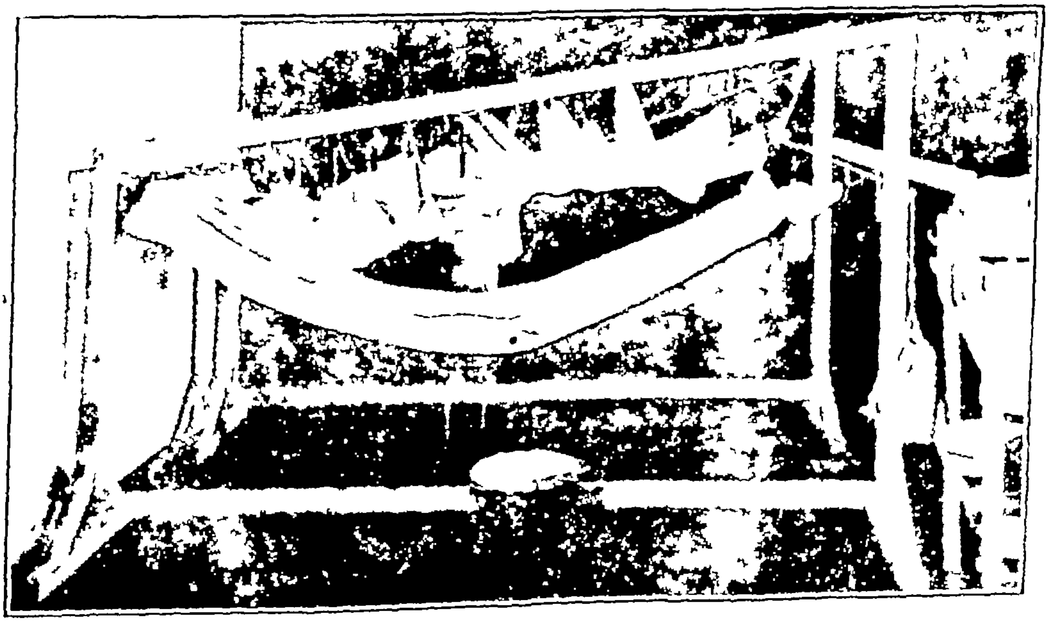
Side view showing abduction extension cord and pulleys attached to projecting limbs of cross bar.

is carried first through a pulley hooked on the upper abduction bar, then through a second pulley fixed to the lower stirrup, and finally through a pulley hooked to the lower abduction bar, ending in a weight which is usually 2 or 4 pounds. As a convenient and easily obtainable weight I make use of one or more ordinary bricks, which weigh about 2 pounds each; every brick is enclosed in a bag, which is hooked by a metal S to a loop at the end of the cord. (Figs. 3 and 4.)

To keep the back of the patient warm a blanket is doubled lengthwise and has strong hooks sewn at the corners, at the middle of each end, and at intervals of 12 inches at the sides. This blanket is attached by its ends to three hooks screwed into the transverse bars at the head and foot of the bed, and its sides are hooked to the side chains to keep it in contact with the patient's body. As many more blankets as are necessary are folded and placed on the top of the first one, six layers sufficing as a rule.

When the wound is dressed the sides of the blanket are unhooked and its lower end is detached and hooked to 9 inch lengths of chain passing

FIG. 5



[illegible] self-draining [illegible]

from it to the hooks on the lower cross bar, thus increasing its length (Fig 5), it now lies suspended several inches below the patient and is used to support a sterile towel, kidney dish, &c Whichever transverse band lies behind the wound is then unhooked from the frame and from its neighbours, so as to expose the dressing In this way the dressing is carried out easily with an extremely slight amount of disturbance of the patient Similar manœuvres are necessary for nursing purposes, the lowered blanket being used to support nursing utensils

Where a continuous irrigation is being used it can easily be adjusted by slitting one transverse band longitudinally for half its length, so as to expose the posterior wound or wounds

An advantage of the hammock bed consists in the fact that the whole frame can be moved without any disturbance of the patient, moving the bed of a patient whose limb is slung from a Balkan splint in the ordinary way is a laborious and painful process Any tendency for the patient to slip towards the foot of the bed is overcome by lowering his shoulders and raising his pelvis, the length of the chains being adjusted at suitable places

The hammock bed which I have described is cheap, taking the place of an ordinary bedstead and rendering mattress, water bed, and air pillow unnecessary It also economises time and labour, as nursing and dressing can be carried out more speedily and with less help than is usual with the forms of bed and splint ordinarily employed

I wish to express my thanks to Lieutenant C H Hopwood, R A M C, for the photographs with which this description is illustrated, and to the nursing sisters who have given me much valuable help

Medical Societies

ROYAL SOCIETY OF MEDICINE

Treatment of Dysentery

A MEETING of this society was held on Dec 20th, 1915, Dr FREDERICK TAYLOR the President being in the chair

The PRESIDENT in introducing Sir Ronald Ross, said that dysentery was a disease which had done almost as much damage as anything in this war Happily, as he understood there had not been very many cases of it in France and the northern area of fighting generally, but at the Dardanelles and in other parts of Europe, as well as in parts of Asia there had been a great deal of the disease Sir Ronald Ross, who had been in Alexandria and had seen a great deal of the disease did not undertake to lay down the law on the subject but hoped to hear criticisms and views from those who had been engaged in treating cases of the disease which had been brought home to this country

Sir RONALD ROSS then delivered a lecture on the Treatment of Dysentery which appears at length on another page

Dr C M WENYON said that for the past two months he had been engaged in examining patients returned from the Gallipoli region by reason of having suffered from dysentery, and he had made 1500 examinations in 500 cases Many of the cases had already been treated with emetine in Gallipoli He found that from 60 to 70 per cent of the returned men had had some kind of protozoal infection and it was very important to decide what form they were suffering from as this was a necessary guide to successful treatment He referred to his recent contributions to THE LANCET[1] on the subject The commonest protozoal infection found in these men was that of the entamœba coli which he believed to be a perfectly harmless parasite The cause of amœbic dysentery was the entamœba histolytica 50 per cent of the cases he saw were those of entamœba coli, while 10 per cent of the cases were harbouring the histolytica, and hence must be regarded as dysentery carriers, they were dangerous to themselves and those with whom they came into contact The actual amœba could not always be found in the stools, but careful search revealed the encysted forms The importance of the latter was not recognised by all, it was believed that in order to establish the diagnosis the free live organisms must be demonstrated The finding of the encysted entamœba was as clear a proof of dysentery as the finding of ankylostoma eggs was evidence of the existence of ankylostomiasis After a four years' study of protozoa which inhabit the human intestine he was able to say that entamœba coli always ran a true course—there was no transmutation, and a person might carry for years without manifesting dysenteric symptoms the amœba of dysentery He had injected it from such people into cats and produced in the latter the typical disease He had also by transferring it from animal to animal, caused dysenteric abscess of the liver Cases had already occurred in people who had never been out of this country He had seen a man recently who was working at the London docks The patient developed liver abscesses and died from the disease, and the necropsy showed the typical cysts of entamœba histolytica The ulcers in the large intestine were not very evident, as they were not more than one third of an inch in diameter It was doubtless through these ulcers that the organisms found their way to the liver Dr Wenyon advocated the careful isolation of carriers and their continuous treatment with emetine, even in the absence of symptoms, because of the danger of their being the means of infecting the community

Dr W J PENFOLD spoke of his experience in examining the stools of convalescing dysentery patients in King George's Hospital. 103 cases were examined, and 47 5 per cent of these gave evidence of previous bacillary dysentery A proper classification of the cases spoken of had not yet been completed All the cases were from the Mediterranean, and the bulk of them became infected in August and September

Dr J W CROPPER said that for some years he had been examining free living amœbæ of the non pathogenic type The jelly method of Dr H C Ross had been employed, and an effort had been made to ascertain why amœbæ encysted, and why subsequently they came out of their cysts The conclusion arrived at by his co worker, Mr A H Drew and himself was that the behaviour of the amœbæ was greatly influenced by the bacteria with which they were associated He thought the different substances used in treatment acted as intestinal antiseptics causing the amœbæ to encyst, and so leaving less of them free to produce symptoms

Dr A NEWSHOLME, C B, spoke of the great value which Sir Ronald Ross's lecture would be to the practitioners throughout the country especially those medical men who were seeing patients returned from the Eastern theatre He was specially interested in the preventive side, and had been much impressed by the estimate that about one-seventh of the cases of dysentery might develop liver abscess That led him to emphasise the value of Sir Ronald Ross's advice to push emetine for all the worth it possessed The happy immunity of England from dysentery before the war, except in asylums, seemed unlikely to be continued and he would therefore like to hear whether there were any effective means of preventing the serious possibilities from becoming realities He concluded by proposing a hearty vote of thanks to Sir Ronald Ross for his paper

Dr F J WETHERED seconded the resolution of thanks, and stated that he had seen a large number of Australian officers who had come from the Dardanelles after having suffered from dysentery Some were from the Medical Corps and he questioned them as to the results of the administration of emetine The answers varied but the majority seemed to greatly favour it He asked whether the means of spread of dysentery was a composite one, was it chiefly fly borne or was it due to diet ?

Dr BRADSHAW expressed his disappointment that neither the paper nor the discussion, so far, had dealt with chronic dysentery because that was the stage of most of the cases in the base hospitals in this country They came with the history of having suffered from dysentery, but otherwise they simply seemed to be subjects of chronic diarrhœa of an intractable kind The anxiety concerning these cases had been increased since the receipt of the War Office instructions that no cases of dysentery were to be discharged from hospital or transferred to another hospital until three negative bacteriological reports had been received concerning them, spread over a period of a month In the South African War he had cases of dysentery which got well on massive doses of ipecacuanha and no liver abscesses supervened later He was anxious to know what was the best treatment for chronic cases which hung fire, the patients not being particularly ill His own favourite method of treatment was by means of castor oil, and he narrated the origin of the use of the oil in dysentery, by missionaries in Barbados, and the references to castor oil at that time did not mention its purgative properties, but simply that it was the best treatment for dysentery He had had very good results from that treatment

---

[1] THE LANCET, vol ii, 1915, pp 1173 12[illegible]

Dr J P S DUNN urged that dysentery patients should not be frequently changed from one doctor to another In some hospitals a doctor who had had experience of dysentery had no cases of that disease under him, they were being dealt with by those who had had no previous experience of it It was also most important that at least one doctor on each hospital ship should have had that experience, though he knew, from his work in the South African War how difficult it was to treat men as well on board ship as on shore And he thought improvement was possible in the direction of giving the patients more complete rest When men were convalescing from dysentery they should not be allowed to get up and go to the lavatory, he believed that custom was responsible for many relapses With regard to diet, he starved his patients for the first few hours, giving only water, with perhaps a little brandy If rapid improvement set in he gave very small meals—egg and a little rusk, this called the masticatory muscles into action, and only the powdered food passed into the stomach Liquid paraffin given carefully and hot applications to the abdomen were important in acute cases, and absolute rest should be ensured He would like to know that an official warning had been issued to the profession in the Empire as to the likelihood of many cases of liver abscess occurring, and advising medical men to be on the look out for them at the same time pointing out the importance of giving doses of emetine

Professor W J R SIMPSON mentioned that Mr Eccles in the Bombay Presidency, treated 22 cases of dysentery with emetine and morphia in 1869 with very satisfactory results But he thought it should be used with care Enteritis had been produced in dogs by large doses of emetine, it seemed also to cause an affection of the nervous system and collapse Small continuous doses of it caused enteritis

Dr MURRAY LESLIE asked whether liver abscess was more likely to supervene in cases of dysentery which showed jaundice He also spoke highly of the value of liquid paraffin in the disease

The PRESIDENT pointed out as a matter of historical interest that Sir William Gull's treatment of dysentery consisted of 5 grains of ipecacuanha three times a day, rest and warmth There was a time when emetine was extracted from ipecacuanha because it was the active principle responsible for the vomiting and it was not surprising that the de-emetinised drug was a failure In the cases of dysentery seen at the Greenwich Seamen's Hospital no organisms were found, they were treated with astringent methods and got well

The resolution of thanks to Sir Ronald Ross was put and carried with acclamation

Sir RONALD ROSS in reply said he regarded cases such as those mentioned by Dr Bradshaw as old cases the chronic cases would be seen in from five to ten years Some of the questions raised would he hoped be settled by the workers at Dr A R Ferguson's central laboratory, Alexandria. He was unable to say how the spread of dysentery could be prevented The bacteria were found plentifully in the sand and among the catacombs—indeed it was known in Egypt as "sand dysentery" There was a real danger of acquiring the disease at the latrines and it was possible to convey it by means of the enema syringe Some of the points raised especially by Dr Dunn would receive attention in the proper quarters

SECTION OF DERMATOLOGY

Exhibition of Cases

A MEETING of this section was held on Dec 16th 1915 Dr J H STOWERS, the President, being in the chair

The following cases were shown and discussed —

Dr GRAHAM LITTLE 1 Granuloma Annulare of one year's standing in a man, aged about 30 who also presented an exaggerated follicular eruption on the lower extremities The questions raised were whether the follicular eruption had any connexion with the granuloma annulare, and whether both pointed to tuberculous disease although no evidence of the latter had been discovered —The PRESIDENT and other members were of the impression that the follicles were not more prominent than they often are naturally —2 ? Lichen Planus The patient had scattered lesions about the body with a well marked serpiginous lesion on one foot As Dr Little remarked the histological examination did not support the tentative diagnosis held The Wassermann reaction was negative —The PRESIDENT, Dr J J PRINGLE, Dr H G ADAMSON, and Dr A EDDOWES considered the case to be of tuberculous origin

Dr KNOWSLEY SIBLEY A case for diagnosis The patient, a man had had for some years polymorphic skin lesions, which commenced on the knuckles, presumably as angio keratomata Elsewhere on the body were verrucose and ulcerative lesions, which on healing left very marked scars The Wassermann reaction was negative and the von Pirquet test uncertain —Dr R M TRAVERS-SMITH considered it to be a case of angio neurosis —Dr J H SEQUEIRA was of the opinion that it was a tuberculous manifestation, due to the presence of circulating tuberculous toxins —Dr ADAMSON was in favour of dermatitis artefacta —Dr A M H GRAY thought that it was a case of persistent dermatitis of unknown cause —Most of the other members regarded it as a tuberculous affection

Dr SEQUEIRA Myxœdema with Sclerodermia The patient a woman aged 56 first came under observation 15 years ago, suffering from myxœdema. Under continuous treatment with thyroid extract (gr i ter omn d) the myxœdema disappeared but two years ago sclerodermia appeared and affected the lower third of both legs The chief interest of the case was that the latter condition had appeared in spite of the thyroid treatment thyroid being a drug which is largely advocated for sclerodermia

Dr GRAY (for Mr WILFRED TROTTER) A case of Recurring Herpes on the right side of the face since one year of age in a girl aged 11 The attacks recurred every two or three months and were always preceded by fever and malaise —Opinions were divided as to whether there was also present a true facial hemiatrophy or merely contraction of the diffused scar tissue and also as to whether the condition was of central or peripheral origin—in other words whether it was a case of recurring herpes zoster or herpes febrilis —Dr SEQUEIRA had a somewhat similar case in which removal of the tonsils and adenoids had cured the condition and other members cited instances in which removal of bad teeth wax from the ears and correction of astigmatism had caused the attacks to cease

Dr G PERNET Acute Involvement of the Soles in a case of Morphœa and Sclerodermia

Dr KNOWSLEY SIBLEY A case of Actinomycosis

Dr EDDOWES A microscopic section which members generally considered to be of a naevoid character—probably a mole

ULSTER MEDICAL SOCIETY

Some Experiences of War Surgery

A MEETING of this society was held on Dec 21st 1915 Dr A G Robb the President being in the chair

Colonel ANDREW FULLERTON A M S one of the consulting surgeons to the British Expeditionary Force delivered an address on the work of the medical officers of the army from his experiences at a [illegible] He explained that the similarity of the work in the [illegible] stations was largely done by the officers of the Royal Army Medical Corps the surgical consultants and specialists being temporary officers selected from the staffs of the civilian hospitals It would be readily understood, he said, that every day there were cases in which a second opinion was necessary, and the system of consultants in his area had worked with the utmost smoothness The more competent the surgeon the more desirous he was of talking over his difficult and dangerous cases with the consultant and the public could be satisfied that everything was being done for the wounded soldier Cases were constantly arising in which it was desirable that the consultant should himself operate, when every facility was placed at his disposal The consultant was, in fact, responsible for all the surgical work done in his district and in his experience he was usually fortunate in the officers over whom he had supervision. He paid a high tribute to the organisation of the Royal Army Medical Corps saying that nothing could exceed the smooth working and efficiency of the machinery which transferred the wounded soldier from the trenches to the base or the hospital ship, as the wounded soldiers constantly testified He then detailed some general lessons of the surgery of the war Sepsis in brain surgery—as, indeed in all branches of war surgery—was he said, the bugbear of the surgeon, and required even more attention than operation Deep searching for foreign bodies in the brain was to be discouraged, and a bullet that was causing no symptoms should be left alone if not easily accessible Persistent hernia cerebri was best treated by lumbar puncture or decompression operations If the patella were shattered it ought to be removed If the lower end of the femur or the upper end of the tibia were badly comminuted it was probably better to amputate at once above the knee The question of the removal of foreign bodies from the knee-joint was a difficult one Rough particles like shell and bullet-casing have probably carried in bits of soiled clothing with micro-organisms and are better removed, but each case must be considered on its merits and the judgment and experience of the surgeon will often be taxed as to the proper procedure Swollen septic knee joints with no fracture and no retained foreign body, offer problems requiring abundant experience, and he made it a point to see every available case and watch its progress He had come to the conclusion that indiscriminate draining of knee joints with tubes was a mistake Fixation, excision of the wound aspiration and washing out with saline, aspiration and injection of such substances as ether, formalin or glycerine, simple incision without a tube packing of the joint with gauze laying open the joint by turning back the patella, with perhaps full flexion of the joint were all measures useful in given cases Failing benefit from any of these amputation was the only resource In the shoulder and elbow excision had been followed by good results In the hip it was occasionally necessary to remove the head of the bone in order to drain the joint and he described several cases in which life had apparently been saved thereby Colonel Fullerton concluded by dealing with the means used in France to immobilise fractures and exhibited the splints in general use, as well as Major Sinclair's apparatus for suspending limbs in splints and Captain Bryan's segmented suspended bed[1]

MEDICAL MAGISTRATES — Mr Arthur Henry Headley Heckle M R C S L R C P Lond and Mr Cecil Christopherson M R C S L R C P Lond have been placed on the commission of the peace for the borough of Hastings

THE LATE DR. ROBERT KINGDON ELLIS — Dr R K Ellis who was fatally injured at a railway crossing at Isipingo near Durban on Nov 20th last at the age of 54 years was a popular member of the medical profession in Durban and district He was at one time Government medical officer in Zululand and later resident surgeon at Durban Hospital At the time of his death he was in practice at Isipingo Dr Ellis was one of the most kind hearted of men and his sudden death is felt as a great loss to the community to whom he ministered He leaves a widow and daughter

Reviews and Notices of Books.

A System of Medicine

By Eminent Authorities in Great Britain, the United States and the Continent Edited by Sir WILLIAM OSLER, Bart M D F R S, Regius Professor of Medicine in Oxford University, assisted by THOMAS MCCRAE, M D, F R C P Professor of Medicine in the Jefferson Medical College, Philadelphia. Second edition, thoroughly revised. Illustrated London Henry Frowde and Hodder and Stoughton 1915 In five volumes Pp 5500 Single volume, 35s the five volumes £7 15s

THE appearance of a second edition of this great System is not only a source of sincere gratification to the editors and to the publishers, as Sir William Osler and Dr McCrae state in their brief preface, but is also a great boon to the medical public

The international character of the System may be gathered from the following analysis of the 96 "eminent authorities" The United States have contributed 74 of these, 11 each from the Universities of Pennsylvania and Harvard, 7 from Johns Hopkins, and 5 from Yale Great Britain follows with 14 contributors, 10 of them from London, 2 (including the editor) from Oxford, and 1 each from Liverpool and Edinburgh Canada follows with 6, five of them from McGill University Germany and Japan contribute one each—namely, Dr W P Dunbar, of Hamburg (Asiatic cholera), and Dr K. Shiga, of Tokio (bacillary dysentery) Six years only have elapsed since the completion of the first edition, and the opportunity of revision has occurred before most of the articles in the System have become seriously out of date The editors say that the revision has been thorough and that certain important changes have been made The new, or practically new, sections will be found on pellagra, beri beri, trypanosomiasis, Malta (undulant) fever, and electrical diagnosis in cardiac disease

A praiseworthy attempt at condensation has been made in spite of steadily increasing subject matter, and this has been carried out by abridging the etiological and pathological sections rather than those on diagnosis and treatment On the contrary, special stress has been laid on these two latter throughout the five volumes The condensation has resulted in five volumes instead of seven, and a total number of about 5500 instead of the 6200 pages of the first edition Each volume is approximately the same size as before, type and paper have been altered, the former is larger, the latter more shiny We are old fashioned enough to prefer them as they were Ease of reference is provided by an index at the end of each volume and a general index at the end of the last As the volumes have apparently been published simultaneously no inconvenience has attached to this arrangement of indexes We question, however whether with a System of this size it is not preferable to have a single detailed general index printed either separately or repeated at the end of each volume Minor criticisms might include the absence of any list of illustrations and of any complete index of authors although the names of these are given at the opening of each volume More serious is the capricious distribution of the illustrations To take an example for the 235 pages devoted to tuberculosis there are but two, one a small graph of mortality returns in phthisis the other a full page plate of a form of apparatus for artificial pneumothorax The articles on small pox and vaccination contain, on the other hand, 11 full page plates

We hope that the editors may consider the issue of a supplement of illustrations to the System They will thus complete the obligation under which they have placed the profession of medicine in issuing a book which is a library in itself and the use of which can often take the place of laborious search through masses of contemporary literature

A Manual of Pharmacology

By WALTER E DIXON F R S , M D Lond , Professor of Materia Medica and Pharmacology at King's College, London, University Lecturer in Pharmacology Cambridge Fourth edition, completely revised London Edward Arnold 1915 Pp 467 Price 15s net

THREE years have elapsed since the third edition of this work was reviewed in these columns[1] What we had to say then in commendation of the work is equally true of this "completely revised" edition—indeed, a perusal of it and a comparison with the previous editions show it to be almost a new volume, so largely have some parts of the text been rewritten This change is due to two causes first, the great increase in our knowledge of the action of drugs, largely the result of experimentation on animals and investigations on surviving excised organs of animals The second cause is that the production of the new Pharmacopœia has necessitated the revision of the materia medica, though it has not entailed the introduction of any new drug which was not described in the earlier editions With the new Pharmacopœia came the introduction of the dual system of dosage It will take some time before the decimal system supersedes the old and more familiar dosage system The number of tracings, already large, has been increased, a few new figures have been added, which raises the total number of excellent well printed illustrations to 91

So far as the arrangement of the text is concerned the number of chapters, their titles, and the list of their contents are practically the same as in the first edition, but an intimate study of the contents of each chapter shows large advances in our knowledge To take for example, the group of cardiac tonics, including digitalis strophanthus, and squill, we find the few pages dedicated to an explanation of cardiac physiology as a basis for the study of cardiac drugs to be most illuminating The exposition on digitalis has been recast, and in the study of its physiological relations the decerebrate animal has been utilised Amongst the vegetable hypnotics the subject of morphine has been similarly recast and rewritten and the same may be said of strychnine In the chapter dealing with drugs acting on nerve endings—e g atropine—some of the pages are practically identical with those in the first edition but in others very considerable modifications and additions have been made Not the least interesting part of this chapter is the author's attempt to explain in a simple manner the mechanism by which such drugs exert their action on nerve endings The printing of some of the tracings in this chapter does not appear to come out so clearly as in the corresponding figures in the first edition

The reader who would profit to the full by a study of this work must have a good general knowledge of physiological methods, as well as be conversant with the results of modern physiological teaching Even many physiologists will find much to learn in these pages No one at the present day can write a good and discriminative text book on pharmacology who has but an imperfect knowledge of modern physiology This work is based on sound physiological knowledge on the part of the author

The fourth edition of this work will add to the high repute which the author has attained in the domain of pharmacology—a repute well reflected in the tersely written and systematic treatment of a subject which in some respects has hardly gained that attention in the medical curriculum which its high practical value demands

Diversions of a Naturalist

By Sir RAY LANKESTER K C B F R S London Methuen and Co 1915 Pp 424 Price 6s

THE authorship of these essays relieves the reviewer of one tiresome duty—the search for error, apt at times to be so prevalent in the popular exposition of science Here we have the leisurely work of our first zoologist, to whom the actual facts with which he deals are known from many years' experience in the field as well as in the laboratory We can, therefore, sit down and read without the obtrusion of any anxious doubt as to the statements

Sir Ray Lankester wanders about in his 41 chapters from place to place, and from subject to subject We start for instance, fairly early in the morning in Sussex, but immediately depart for Norway to dredge for rhabdopleura in a deep fjord Rhabdopleura duly dredged up and pickled for future reference, we hasten back to Sussex to consider the fragmentary skull of primeval man This discovery leads us to a dissertation on the ape brain and the ape mind and by a not unnatural transition, to divining rods and other examples of the unintelligent or dishonest divagations of the human brain Upon all of these latter topics the author is crystal clear, permitting no haze of any kind He sees only sheer swindling or ignorance Moreover, a detailed account of the processes adopted in a particular case by an alleged expert in the use of the divining rod is given as a proof of the necessity for this uncompromising attitude Many of the articles are quite purely zoological and the eminent writer does a useful work in bringing clearly before the lay reader the salient facts in the history of the barnacles, the classification of crustaceans the mode of life and organs of the living body among worms and such like topics The less instructed reader will delight in such chapters as that on amber To many of us probably to most of us the idea of blue amber is a novelty [illegible] the author comments upon the fact that this fossil resin is not always yellow or golden but occasionally deep red and even blue Sir Ray Lankester reminds us that amber is mentioned in Homer it is mentioned as forming a [illegible] of [illegible] in the Odyssey forming part of a gold necklace Its [illegible] was doubtless due to the fact that [illegible] then as now the chief source of supply [illegible] sources of [illegible] amber [illegible] we learn from Sir Ray Lankester [illegible] African copal and the [illegible] times be found [illegible] substitute

---

[1] The Lancet [illegible]

There are other matters on the outskirts of zoology with which the author concerns himself in the same interesting way The legend of the origin of the Bernicle goose from the barnacle receives some highly readable comment Sir Ray Lankester scoffs at and rejects Max Müller's explanation of this myth, and terms it "an excellent case of the misuse of hypothesis" The Brent goose, thought Max Müller, was called Berniculus by the clergy as a diminutive of Hibernicus—a "little Irishman" in fact This appears, however, to be a sheer invention, and was made to explain the legend instead of the legend explaining any fact The author himself is not so bold as Max Müller in any attempted explanation, but he quotes from students of Mycenæan pottery who have at any rate shown that in the ornamentation of this pottery a leaf of a tree is gradually converted into the similitude of a goose and also of a barnacle—thus is the Irish legend of monkish origin largely antedated We are inclined to believe that the story of Dick Whittington's cat, quoted by Sir Ray Lankester as a just instance of the origin of a legend from the change of meaning of a word, has not the significance which he thinks He holds that the Norman French "achat," very likely pronounced "acat," which means commerce, was, indeed, the origin of Dick Whittington's fortune This view can be traversed The domestic cat of this country, which is not the offspring of the European wild cat, was introduced, and was a rarity at one time The derivation of the word puss, which has been held to be from Persia, or from Pasht, or Bubastis, is indicative of the non English character of the cat Association with a cat was a sign of wealth, as witness the evergreen story of Puss in boots

Sir E Ray Lankester's diversions make thoroughly amusing reading

---

Life A Poem

By BASIL GORDON MORISON, M D With a Preface and Biography of the Author London Baillière, Tindall, and Cox 1915 Price 3s 6d net

To those who know Basil Morison this little volume, which contains also a biographical memoir of the author will be of value for his sake, and to others who did not know him it may show the manner of man that he was From the preface we gather that the poem was written, probably in the last year of the author's life, to give concrete expression to ideas on which he had pondered long and deeply The day before his death—which he knew was imminent, and which he regarded with unruffled composure—he told his wife that he had written a few verses "which might be considered worth publishing The poem takes the form of a dialogue between man and the spirit of life In its opening verses it describes the course of normal and happy human existence in a measure which recalls the cadence of Gray's 'Elegy,' while many of the verses are reminiscent of Omar Khayyam, although the philosophy expounded differs wholly from that of the writer of the 'Rubaiyat' If his life had been prolonged Basil Morison might have been inclined to extend and amplify his theme and to finish the poem on a yet more exultant note of assurance Such stanzas as the following show that although Morison turned late to metrical form, he had much facility in that medium

A PRAYER

Lord of Thy [illegible] and Thy power
[illegible]
[illegible] the hour
[illegible]

Resolved, and calm, not slow, nor fain
In weakening doubts to stay,
Alert yet so that I retain
Thy guidance, and obey

Deny me pride that seeks a fall,
Forbid servility,
Give that most gracious grace of all,
Give me humility

A friend of Morison writes to us as follows of the book "To one who has lived more than half his life in Stoke Newington, and who was honoured by his unbroken friendship for more than 30 years, the Memoir is especially interesting The 'Smallest Borough in London' has always been proud of its literary associations, to which another is now added, while, to very many of its present inhabitants the sunny smile, the ever cheerful greeting, and the overflowing vitality of the author of 'Life,' will be a happy and abiding memory"

JOURNALS

Journal of Anatomy and Physiology Conducted by Sir WILLIAM TURNER, K C B, Professor ALEX MACALISTER Professor ARTHUR THOMSON Professor ARTHUR KEITH, and Professor ARTHUR ROBINSON Vol L Third Series, Vol XI, Part I October 1915 London Charles Griffin and Co Annual subscription, 21s post free —The longest and most important paper in this issue is one by *Professor J E Frazer and Dr R H Robbins* on the Factors Concerned in Causing Rotation of the Intestine in Man The subject is a very wide one and the title itself suggests an initial comment for it is obvious that no explanation can be concerned with this rotation in man alone, the underlying factor which operates in man must be capable of application to the mammalia generally It appears to be a merit of this paper that the greater part of it is capable of standing the *strain of* this wider extension Two distinct problems are involved in this study first, the primary fixation of definitive portions of the alimentary canal, and secondly, the causation of rotation in the loop dependent between the primary fixed points The first question has been given a wider significance even in the short while that has elapsed since the reading of this paper, and it is one destined to be carried yet further The second question we imagine the authors have largely solved, in some if not in all of its distinctive stages —Professor Arthur Thomson contributes a long and exceedingly well illustrated paper upon the Presence of Genial Tubercles in the Mandible of Man and their suggested Association with the *Faculty of* Speech The article deals with far more than the mere presence of these tubercles for it is a study of many features of the lower jaw, and it might be *added* that research of this magnitude is hardly needed to demonstrate that the human faculty of speech has nothing whatever *to do* with any trivial moulding of the mandible The whole structure and variations of the region of the symphysis receive ample treatment, and the paper is a valuable record of the conditions present in a very large series of cranial types But it is perhaps, a pity that the author should create an impression that such *an elaborate* research valuable for its own sake was necessary to determine if a cerebral evolution like the power of speech depended on the mechanical presence of these inconsiderable features —A paper upon the Homologies of the Chelonian and Mammalian Types of Genitalia by *Professor F Wood Jones* continues and sums up the previous articles in the journal contributed by the same author The writer contends that from the Chelonian condition mammalian evolution in respect to the genitalia has taken place along two lines which result in distinct types *of adult* external genitalia The paper is illustrated by drawing of actual embryos —Mr F J F Barrington contributes an article on the Mucinous Changes of the Vaginal Epithelium of *Certain* Mammals in Pregnancy The changes as shown by the excellent coloured illustrations are distinct enough and are obviously of some very real functional importance But as the author shows there is a bewildering inconstancy from species to species *and* even among individuals of the same species that tells plainly that more work is required in this field before we may draw definite conclusions —Mr W E Collinge records and illustrates an interesting and valuable series of abnormal developments in the vascular system of the frog, and most of these anomalies obtain a ready explanation from the known stages of development of the vascular system —A paper upon the Developmental Changes in the Pericardium, the Mesocardia and the Pleural Sacs of the Human Embryo, by Professor David Waterston, deals with some difficult problems in embryology The paper is illustrated by drawings of reconstruction models, and since these models have been placed upon the market they are open to further study and comparison with earlier and later stages of the human embryo

Reports and Analytical Records

FROM

THE LANCET LABORATORY

THE EDINBURGH ANTISEPTIC EUSOL

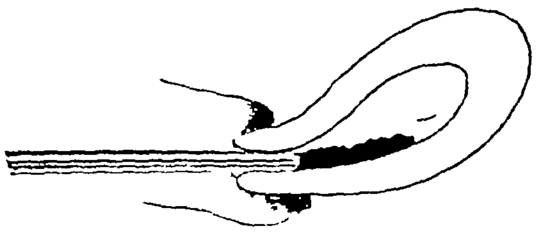
(MESSRS DUNCAN FLOCKHART AND CO , 104, 106 108, SOUTH CANONGATE, EDINBURGH)

THIS enterprising firm has hit upon a convenient way of extemporaneously preparing a solution of hypochlorous acid for antiseptic purposes They issue a case containing packets of boric acid and of chlorinated lime respectively Of course, chlorinated lime is very susceptible to deterioration under the combined influence of moisture and the carbonic acid of the air This deterioration is successfully prevented by packing the bleaching powder in heavily waxed paper The claim that the activity of the chlorinated lime is thus preserved is substantiated by our examination Thus we found that the available chlorine present amounted to 29 82 per cent This approximates to the French standard of 100° of chlorine gas Since hypochlorous acid is the active agent concerned, we are led to believe that bicarbonate of soda might well be substituted for the boric acid, with the additional advantage that it would have acid neutralising properties When bicarbonate of soda is mixed with chlorinated lime the solution contains hypochlorous acid in spite of the presence of the bicarbonate The fact is that hypochlorous acid is easily expelled by carbonic acid from the hypochlorite If it were not so, bleaching powder would be of little use employed in the ordinary way, since it is not until the carbonic acid in the air acts upon it that its disinfectant and antiseptic properties become potential

IODARGOL UTERO TOPIQUE

(MESSRS M BRESILLON AND CO GAMAGE BUILDINGS, HOLBORN, LONDON, E C)

The value of iodargol in obstetrics has been often asserted and good results in certain uterine affections might be anticipated in view of the fact that iodargol presents iodine in colloidal form An apparatus for the treatment of metritis and known as the utero topique has recently been introduced by M Bresillon and Co Its action will be understood from an inspection of the accompanying illustration It consists of an injection tube or cannula attached to a collapsible metal container in which is the supply of iodargol in a jelly like medium This is expelled in a quantity under complete control by a key the rolling over of which gradually discharges the contents The illustration shows the cannula in position in the cervix The cannula is grooved in order to allow of the escape of air as the cannula enters Iodargol has been used for general antiseptic treatment of both the male and female genital passages



(1) "TABLOID" SODIUM ACID SULPHATE (2) COMPOUND MENTHOL SNUFF

(MESSRS BURROUGHS, WELLCOME AND CO SNOW HILL BUILDINGS, LONDON, E C)

1 The bactericidal action of sodium acid sulphate deserves more attention than it has hitherto appeared to have received It is very rapid in destroying the typhoid organism, and this should render it of great service to the soldier in the field He has only to add a tabloid of sodium acid sulphate to a pint of water and leave it for half an hour when he can be confident that the water is safe to drink The slight acid taste which the addition of bisulphate gives is not objectionable, and in the tabloid a small amount of sweetening agent is present which renders the water palatable 2 Compound menthol snuff is well known as affording relief in the treatment of common colds, nasal catarrh and so forth, but its application has been materially improved for export purposes by packing it not in metal boxes, but in a watch shaped glass bottle This preserves the menthol intact, and is particularly suitable for use in tropical countries

VITAMOGEN

(MESSRS WILLIAMS AND CO 24-26, HOLBORN LONDON, E C)

The name of this preparation implies the presence of the so called vitamines It is difficult to confirm chemically any claim on this ground since the chemistry of vitamines has not yet been definitely settled and the particular substance extracted from yeast and the outer layers of rice gives so far as we are aware, no definite chemical reactions Following, however, the method enjoined for the extraction of vitamines from substances containing them, we obtained an alcoholic extract from vitamogen after fat had been removed, which gave distinct evidence of the presence of a basic body Vitamogen contains all classes of food as shown by our examination—proteins, carbohydrates, fats, and mineral salts rich in phosphates According to recent work vitamine is a base and not a phosphatide We do not know how vitamogen is prepared but presume that it contains vitamine extracted from a vitamine containing food product which might be yeast or a cereal We found starch cells present The particular claims of the preparation can only be proved by practical trial and it seems worthy of such a test

PROPHYLAXIS AND TREATMENT OF HAY FEVER BY "POLLACCINE"

Hay fever is the poisoning produced by the pollen of certain plants when it comes in contact with the mucous membrane of susceptible individuals In this country the pollen usually responsible is that of Timothy Grass (phleum pratense) The condition can be diagnosed by (1) its characteristic symptoms, (2) its periodicity, occurring when grass is in flower and not at any other time, and (3) by a characteristic ophthalmo reaction

In using "Pollaccine" it is highly desirable to make a specific diagnosis because it is useless to immunise against pollen unless pollen is actually causing the symptoms from which the patient periodically suffers When an extract of grass pollen is dropped on to the eye ball of a normal individual at any time of the year no effect is produced, but when it is dropped on to the eye ball of a periodical sufferer from hay fever the conjunctiva becomes inflamed and the patient begins to experience sensations of an attack of hay fever *The difference between the normal and the susceptible individual constitutes the diagnostic reaction* A positive reaction involves only slight and transient conjunctival or nasal irritation to the patient, quite unlike the rather serious consequences sometimes following the tuberculin reaction

For the purpose of carrying out the hay fever ophthalmo reaction an Outfit is supplied containing 7 dilutions of pollen extract in sterile hermetically sealed glass tubes "Pollaccine" contains carbolic acid and is therefore unsuitable for taking the ophthalmo reaction Not only does the ophthalmo-reaction give a specific diagnosis but the strength of the extract which just produced the reaction will be a guide to the suitable dose for inoculation

Prophylactic Treatment —The best prophylactic dose is one third the number of units which just produced the ophthalmo reaction, and the dose should be given every 10 or 14 days It is recommended that in very severe cases prophylactic treatment should be commenced in the early winter the milder cases being allowed to commence treatment later in the winter or even in the spring While one can say with confidence that a prolonged course of inoculation, given regularly, will almost certainly stop or profoundly modify the attacks of hay fever, it is much more difficult to say what is the minimum of inoculations necessary to bring relief There is usually only slight local reaction at the site of inoculation and no constitutional disturbance after the dose The only serious discomfort to be apprehended is an attack of urticaria and this can be cut short by one or two doses of calcium lactate 20 grains

As already stated it is desirable to make the specific diagnosis before commencing prophylactic treatment in any case but if it is advisable to try inoculation treatment without the help of the ophthalmo-reaction then the only guidance is the average reaction of hay fever patients during the winter The following shows the percentage of cases in which the ophthalmo-reaction [illegible] and the amount of "Pollaccine" to be used for prophylaxis —5 [illegible] of pollen extract react in 2 of cases and the prophylactic dose is 2 units, 15 units react in 4 of cases, dose 5 units 50 units react in 19% of cases dose 15 units 150 units react in 45% of cases dose 50 units 500 units react in [illegible], of cases dose 150 units 1500 units react in 6 of cases dose 500 units, 5000 units are rarely required to produce a reaction, and in no case should more than [illegible] be given for a prophylactic dose

Therapeutic Inoculation — The ophthalmo reaction not only gives the diagnosis but also indicates the correct dose If it is desired to try therapeutic treatment without the help of the ophthalmo reaction, the guide to dosage is the ophthalmo reaction of hay fever patients during the summer It is found that the best therapeutic dose is one tenth the number of units which just produce the ophthalmo reaction thus as the majority of [illegible] react with 50 units 5 units of "Pollaccine" is the average dose It is found that during the summer the ophthalmo reaction is produced by 5 units in 8 of cases and the proper dose of "Pollaccine" is ½ unit 15 units in 19% of cases dose 1½ units 50 units in 44 of cases dose 5 units 150 units in 21 of cases dose 15 units 500 units in 7% of cases, 1500 units in 1% of cases 5000 units very rarely required for reaction In the [illegible] cases the appropriate dose is 50 units

Preventive treatment in the winter is however more effective and more to be recommended

No guarantee can be given that the "Pollaccine" of one year will be identical in strength with that of a previous year "Pollaccine" prepared from the 1915 crop of season [illegible] pollen is slightly stronger than was that of 1914 [illegible] commencement of this year no "Pollaccine" [illegible] out other than that prepared from 1915 pollen [illegible] "Season 1915" is stamped on all the labels of "Pollaccine" obtained from this crop

"Pollaccine" is prepared in the laboratory of the Department of Therapeutic Inoculation [illegible] Paddington London and [illegible] following dilutions —5 units 20 units 100 units and 5[illegible] units at 2/9 per bulb and 2 [illegible] at 27/9 per bottle

The Hay Fever Reaction Outfit containing 7 [illegible] tubes of pollen toxin in graduated dilutions [illegible] for instillation into the patient's eye [illegible] 5/6 [illegible] 2 [illegible] 1/6 per [illegible]

THE LANCET.

LONDON SATURDAY, JANUARY 1, 1916

Thrift.

ONE great message of the new year is the need for thrift The press has been considerably occupied of late with the subject, and especially of thrift in connexion with the sphere of women as the stewards of home life, but there is not so far much evidence to show that any of us, males or females, have taken to heart the widespread injunctions to economise And yet it is increasingly evident that victory may be largely decided by thrift As the war has gone on the organisation for spending in all departments has become more elaborate, no similar organisation for saving has been attempted And we confess that organised national thrift is difficult to contemplate, so far as it takes the form of domestic economy, for that is a thing which in this country is quite individual But it is a serious question whether it should remain so, or whether an attempt should not be made to instruct the public in some authoritative manner upon how to get the best values for a modest expenditure There may be no sort of need in this country for ' fatless days ' or " meatless days,' but we are spending weekly the revenue of a respectable province, and with the many adjurations to economy emanating from the bench, the pulpit, and the inkstand there has seldom been combined any accurate scientific advice It is only necessary to pay a visit to the manufacturing towns of the West Riding of Yorkshire to see how reckless is the expenditure in consequence of the great trade boom which is still going on there The standard of living has increased in the last 12 months, and we have been told that the sale of pianos and motor cars testifies to the great profusion which exists This may be picturesque reporting, but we hear too that in many parts of the East of London investment has taken place of late in furniture and even in jewellery rather than in war stock In willingness to economise and to place individual resources unhesitatingly at the service of the State we fear that we are very greatly behind Germany

In Germany before the outbreak of war the necessary measures for household economy were widely known and they were put into practice immediately on the commencement of hostilities In a few months there appeared a comprehensive scientific study of the problems presented by the feeding of a nation, written not exactly for popular reading, but so that any scientific person could explain to the public the principles of economic food supply A summary of the book appeared in our columns,[1] the book itself being subsequently done into English with a preface by Professor A D WALLER The public press quoted freely from our summary at the time, but rather with the idea of calling attention to the success of the British naval blockade than of pointing to the value which such domestic organisation might prove to possess We would suggest a restudy of the document now to draw from it what instruction we may Our need for thrift is not as urgent as that of our enemies, but economy means money and a quicker end to the war The medical profession might lead the way in a thrift crusade, and perhaps the medical women are especially indicated to undertake this great task, but we do not know that the public is looking to us for initiative in thrift, or would find a united profession on the subject Here, indeed, there is room for drastic improvement The value of foodstuffs is now established on a scientific basis, and food can be measured in heat values without any risk of gainsaying The story of a district council, acting on medical advice in refusing to sanction the use of margarine instead of butter in their tuberculosis pavilion, is unfortunate at the present time, and Dr A NEWSHOLME was stating a well established fact and not merely his own opinion when he wrote —" There is no reason to suppose that margarine is less nutritious than an equal quantity of butter, and it certainly has no harmful or deleterious effect " When he added " I am using margarine in my own household, we imagine that he was merely saying what would be the practice of every household in the land that had given any intelligent consideration to food economy HINDHEDE has recently fed two workmen over a period of many months on potatoes and margarine only, and has kept them in good health on this sufficient but unattractive diet Fortunately in this country with its free imports there is no practical risk of being condemned to a diet of such monotony as this, but none the less the need for avoidance of all useless extravagance is the same Much is heard of the hardship of the employment of war bread by the Central Powers but no one who has ever grasped the value of a more complete utilisation of the germ than in our invariable white bread will ever consent to continue to waste so much of the valuable part of the grain Before the war the reason for the growing prevalence of white bread in Northern Germany was one of economy, based on LIEBIG's teaching that the outer layers of the wheat grain were better utilised by the pig and the cow, and thus indirectly as pork and milk, than directly by man himself Now that wheat cannot be in Germany legally given to cattle and pigs in any form, this theorem has been disproved, and there is no difference of opinion as to the value of the 75 per cent ground wheat. If we continue our preference for white bread we should at least make sure that the rest of the grain is really used for fodder.

---

[1] The Food Supply of the German People THE LANCET Feb [illegible]

Thrift does not consist solely in eating margarine and wholemeal bread, although this would mean a great deal if the saving were invested in War Loan. The whole diet sheet should be intelligently supervised and, if need be, amended. And in so doing we should like to call attention amongst other guides to an admirable pamphlet[2] by the professors of agriculture and of bio chemistry at Cambridge. There we read that "Comparing the expenditure of the poor with that of the well to do, we find that the former get nearly twice as much for their money." *Here is the opportunity for the woman of the well to do household to give* her family the same amount of nutritive material whilst at the same time crediting much of the usual expenditure to her savings bank account. We believe that the medical profession, and especially the medical women of the country, could organise a thrift crusade on healthy lines, and are sure that in so doing they could command the finest and most willing scientific advice, but such a movement would need the full support and coöperation of all local authorities so as to remove the slightest suspicion of medical dictatorship. Further, we believe that the time has come, and indeed has been upon us for some months, when a national movement should be made in this direction.

◆

Wounds of the Abdomen

THE treatment of wounds of the abdomen remains one of the most difficult problems presented to the surgeon during the war. On the one hand, he cannot rely on the experience of the past, and, on the other, the lesions which may be produced vary enormously, they may result from the swiftly moving rifle bullet, the less rapid fragment of a shell or the shrapnel bullet, or may be the result of the almost spent projectile or the thrust of the bayonet. The experience of the past will not aid the surgeon greatly, for not only is the violence of the wounds inflicted greater than that met with in previous campaigns, but the conditions are considerably different, because of the number of the injured brought to the surgeon at one time. In this war of huge armies the crowds of wounded arriving after an engagement may be so great as to tax to the utmost the resources of any hospital and abdominal wounds in particular require for their treatment some time for reflection and some elbow room. In THE LANCET last week we published the Bradshaw lecture by SIR ANTHONY BOWLBY upon this subject and in the previous week an important paper by Colonel CUTHBERT WALLACE. This week we publish a further paper by Captain W C B MEYER and Lieutenant D C TAYLOR, a note to this last paper having been written by SIR ANTHONY BOWLBY. All this material gives us ground on which to reflect with a view to arriving at solid deductions. It is, of course, only penetrating wounds of the abdomen which we are considering, for a wound of the abdominal wall which does not penetrate beyond the superficial structures is usually of little importance. Now it may be difficult, and sometimes it is even impossible, to determine with absolute certainty whether an abdominal wound does or does not penetrate, and therefore statistics as to the number or proportion of wounds of the abdomen, as compared with injuries of other parts of the body, cannot be absolutely exact, and a comparison of the effect of expectant and operative treatment must always be to a small extent vitiated by this fallacy. Nevertheless, we can gain a fair idea as to the relative frequency of these injuries, and we find that in "field ambulances" we meet with a little under 2 per cent of abdominal injuries, while in "casualty clearing stations" the percentage has fallen to about a third of this number. Colonel WALLACE accounts for this reduction in the percentage by the very heavy mortality amongst abdominal cases at field ambulances, so that a large proportion of the injured never come to the care of the surgeons at the clearing stations. At all events, it is clear that the percentage of cases of abdominal injuries which will come under the care of the surgeon for operation is not great though he may be hampered in their treatment by the vast aggregate of the wounded.

At the beginning of this war the treatment adopted was under the influence of the practice employed in the South African War. Very few cases were submitted to operation, and the results then obtained were not calculated to increase the number of cases in which such submission would appear advisable. After a time the results of post mortem examinations showed that a number of cases had died in which a timely operation might certainly have saved life, and gradually operations have come to be performed in a higher percentage of cases. The communications to our columns already cited give a striking account of the results which have been obtained up to the present, and suggest perhaps more optimistic views than have hitherto been held. Both post mortem examinations and operations have shown that by far the most frequent cause of death is hæmorrhage and it is also clear that if the patient does not die from hæmorrhage he will almost certainly die from peritonitis if the intestine has been opened by a bullet or a fragment of a shell. But we also learn that it is possible for a bullet or a fragment of a shell to traverse the abdomen without wounding the bowel and that even many wounds in which perforation appears to have occurred are not penetrating wounds at all. The [illegible] tables which are attached to the paper by Captain MEYER and Lieutenant TAYLOR show that operations were performed in only about half of all the abdominal cases admitted in the district, in some cases this was because the patients were moribund and past help, but in other cases because an operation was not considered necessary, and this opinion was certainly justified by the fact that not one of the patients died for whom no operation was thought necessary Operation appears to be least necessary with wounds in the epigastric or hepatic regions, especially in antero posterior wounds, if no definite symptoms are present, but if there are any signs of continuing bleeding, an operation must be undertaken A wound of the stomach is less likely to be followed by peritonitis than a wound of the small bowel, for the mucous membrane of the small intestine pouts into the wound and increases the risk of peritoneal infection, while the gastric mucous membrane does not protrude Therefore, a wound of the stomach is in itself less serious than wounds of the small intestine SIR ANTHONY BOWLBY points out that all wounds without exception which seem likely to involve the area of the small or large intestine should have an exploratory operation and this should be followed by a laparotomy if the peritoneum is found to be wounded. That is one great lesson we have now learned An operation should also be done in all cases of wounds of the gluteal and lumbar regions where the symptoms point to a visceral lesion The statistics show that out of a total of 50 abdominal cases the stomach or intestines were wounded in 34, and of these patients no less than 21 recovered It is almost certain that not one of these patients would have survived if no operation had been performed

---

[2] Food Economy in War Time. By T B Wood, M A, Drapers Professor of Agriculture, and F G Hopkins, M A, F R S, Professor of Biochemistry. Cambridge University Press. [illegible]

To sum up the present situation When the hospital facilities are obtainable, and when the patients can be seen within a reasonable time of the infliction of the injury, a patient who has a penetrating wound of the abdomen should have a laparatomy performed, and then he will have the best chance of recovery, whether he is suffering from hæmorrhage or from perforation of a hollow viscus Undoubtedly, many cases will die in spite of the operation, but a large proportion will be saved who otherwise would have succumbed either to the loss of blood or to peritonitis Where the conditions will not allow an abdominal section to be made because either time or facilities are wanting, then the best that can be done will be to keep the patient without food for several days Then some of these cases will recover, but it will in almost all cases be impossible to be sure that any wound of abdominal vessels or viscera has occurred It is yet early to expect statistics of a large number of cases but before long we shall be able to learn with more certainty the effect of early and skilled treatment of perforating wounds of the abdomen Our impression is that we shall receive gratifying information

The Supply of Medical Men for the Army

THE position of medical men with regard to the needs of the army remains the most momentous professional question of the hour With our fighting forces shaping towards the vast total of 4,000,000 it needs no imagination to see that the resources of medicine, of surgery, and of scientific sanitation in all its branches are going to be heavily drawn upon The public was reminded by a letter which appeared on Dec 16th last in the columns of the *Daily Telegraph*, signed "M D, F.R C S," that the question of how sufficient medical men are to be found for the army is one which concerns the whole population of the country rather than the army or the medical profession only, and though we do not think that the letter itself was a particularly useful or well informed one, we welcome its underlying message The reminder was not required as far as THE LANCET was concerned We have throughout been insistent on due thought being taken for the needs of the civil population, and have given at different times reasons for our views which we do not repeat, for they were so obvious that most will guess them Truly, it may be assumed that all medical men, all military authorities, and all leaders of political or social thought desire exactly the same things—success to our armies, and the safeguarding, at the same time, of our civilian population from the worst of the ills attendant upon the war Those who are not in agreement so far can be left out of all count, while the only difference of opinion existing between the rest of us turns upon the question to what extent the civilian population shall be sacrificed so that the naval and military forces may make good their endeavours to set right the monstrous evils that have been thrust by German ambition upon Europe

The War Office has said, and the War Office continues to say with increasing emphasis, that more medical men are required for the army It is perfectly easy to reply that the War Office is in error, but it is not so easy to see how those who make this reply come to be possessed of the complete information necessary to support their position, or to understand why the War Office should deliberately embarrass the medical profession by making untrue statements Some weeks ago the Central Medical War Committee, when that body was recognised by the War Office as the official recruiting medium for the medical profession, was warned that 2500 medical men would be wanted for the army early in 1916 Since then the Prime Minister has foreshadowed an addition to our army of a million men If some 2500 medical men were required with the army *before* this pronouncement, we may be certain that at least 3500 or 4000 are now required, unless complete reorganisation of the Army Medical Service can be contemplated at the present juncture At the same time there are signs that the civilian population is feeling the shortage of medical men, though to what extent it is difficult to say From some localities one story comes, from other localities another It is certain, however, that for a long time institutions of all sorts have been unable to obtain resident officers, and that public authorities have been obliged to put up with depleted staffs and to restrict their energies accordingly Now everyone can see that there is here a point at which danger to the country as real almost as danger from the presence of an armed foe, might come from the absence of proper medical and sanitary precautions at home It is imperative that the public health of the country should be kept in a good state, if only that munition workers and those directly concerned in supporting the effectiveness of our army and navy should enjoy good health, and that recruits should be drawn from wholesome sources Let us place this demand on medical service, if only for the sake of argument, as in no respect second to the direct demand of the War Office, and the position is at once clear—there is only a limited supply of doctors, urgent claims are made upon them in two directions, and economical use of them is the only way out of the difficulty But no one can say, If you take precisely this number of doctors away from the civilian population you approach or pass the danger point And similarly, no one can state that the army requires an exact number of medical men by an exact date—the War Office attempts no such excursion into prophecy when demanding increased medical assistance All that can be done is to husband resources, and to apply to the situation the rule that must be observed in every other set of circumstances while we are under the tyranny of this war namely, that during the adjustment of supplies the civilian population must go short—quite short, if need be, so that the army may be well supplied—quite well supplied For in civilian situations there is time to cope with emergencies while military needs are invariably urgent and have to be met in excess of probable requirements as the only way to guard against surprise The phrase "too late has occurred rather frequently in explanatory speeches dealing with our military undertakings, and it should be the ambition of every medical man to see that in no circumstances can these words be applied to medical recruiting

We may fairly urge upon the War Office the need for making every reform that is possible so as to use with the nearest approach to parsimony that is safe the quota of medical men who can be spared from civilian needs But we must not assume that, because somebody knows of some place or other where the medical officers are for the moment but lightly tasked the demands of the War Office are disingenuous and could be met by a little re-shuffling of the supplies in their hands The army must be made safe it should be sheltered from the dangers that can be estimated, and should possess reserves with which to meet the unexpected Therefore the civilian population must be prepared to endure sacrifices This is a side of the matter which is not sufficiently recognised, and the sooner it is understood by the public the better That same public which can no longer walk with ease and safety about the streets because the supply of lights is curtailed, which can no longer call for its pipe its bowl, and its fiddlers without much closer restrictions than in times of peace, will have to learn that medical attention can be given in a perfectly adequate manner by a smaller number of medical men than is usually available if the people will help in every way to spare the depleted ranks of medicine unnecessary trouble It is inconvenient to have to wait a long time for a doctor, it is disappointing not to obtain the services of the preferred man it may be a tragedy for an operation to be postponed These things may have to be endured The work of public authorities cannot be so comprehensive when the staffs are inadequate, but some of the medical energies of these authorities are spent in correcting the errors of the public, who must take greater heed on their own initiative to the rules of sanitary life We know that the National Health Commissioners are under a contract with regard to panel patients it may be that the panel patients will not obtain all that they consider they have been promised but we are certain that the medical profession is doing and will do all that is possible in the existing situation

Annotations.

Ne quid nimis.

THE INFLUENCE OF ALTITUDE ON THE NERVOUS SYSTEM

IT appears from an interesting communication in the *Aeroplane*, under date Dec 15th that certain officers of our flying service have suffered from some intangible disease which for lack of more definite diagnosis is put down as neurasthenia the functioning of the patient's nerves is so affected as to make him incapable of flying safely or usefully, he crashes his machine every time he lands or his eye is spoiled for observing or shooting Such symptoms are usually summed up by saying that the man is off his form but the writer specifies other symptoms of a more precise nature These have been referred to also in a recent number of the *D[illegible]* [illegible] *Presse* under the name [illegible] [illegible] are said to be caused mostly by rapid changes of altitude whereby the differences in air pressure and temperature make themselves seriously [illegible] ing headaches ear drumming, and [illegible] ing An aviator [illegible] lands in a state of complete [illegible] and physical collapse His head is splitting [illegible] intolerable pains [illegible] account of the [illegible] into which the [illegible] automatically falls The [illegible] mentions the occurrence of severe pains in the eyes, and declares that the sleep above referred to is like a drugged sleep, so profound is it. It appears, further, that when service flying usually took place at heights of 3000 to 4000 feet these cases did not present themselves, whereas since "improvement in anti-aircraft guns and gunnery has made 10,000 feet an ordinary reconnaissance height, and 12,000 to 15,000 a common height in crossing enemy lines" the question of variations in pressure and its possible relation to this curious pathological state obviously become matters worthy of serious attention. The writer in the *Aeroplane* makes the interesting suggestion that possibly the disease is an exact inversion of caisson disease, not occasioned, however, by excessive or insufficient pressure, but by sudden differences of pressure. An aviator will come down with a speed frequently exceeding a hundred miles an hour, at an angle of "one in one," so that "it is possible that the change from the low pressure at 10,000 or 12,000 feet to ground level in a few minutes may produce precisely similar effects to that produced by excessive pressure when diving."

After years of controversy and conflict of theory it has been established by exact experiment that the cause of caisson disease is that nitrogen dissolved in the body under pressure forms bubbles on sudden decompression and obstructs the circulation. From the most trifling disturbance to sudden death all symptoms alike are thus produced. It must be noted that it is the partial pressure of nitrogen in the atmosphere and not the general atmospheric pressure that is the important factor. P. Bert, for instance, exposed an animal to high pressure in an atmosphere poor in nitrogen and rich in oxygen without any untoward result, though decompression was rapid. Dr. Leonard Hill has shown that other factors are of great significance. Thus, it is not compression but decompression that gives rise to symptoms. Compression up to 4½ atmospheres is not in itself to be feared; the return to the normal pressure is alone to be dreaded. "The risk is proportional to the period and degree of compression and to the rapidity of decompression" (Hill). Where the activity of the circulation is great enough the nitrogen surplus will be carried away and escape by the lungs, whereas where it is slower and where the tissues are fatty—since fat absorbs five times as much nitrogen as water—the risk of bubble formation is very great. It is for this reason that the familiar "bends" occur in relation to joints and fasciæ, and that the white matter of the spinal cord is commonly involved. From the rapidity of the circulation through it brain symptoms are scarcely ever met with in caisson disease. Hill has also demonstrated conclusively that the pulse-rate, the blood pressure and respiration are but little altered by air compression *per se*.

"Flying sickness" in its more essential particulars is rather removed from caisson disease and is deserving of careful clinical and scientific investigation. It raises matters of interest in connexion with so-called mountain sickness. Edward Whymper stated from his own experience of this condition that the abiding symptoms are profound lassitude, intense headache, feverishness, accelerated respiration and occasional spasmodic gulping of air "just like fishes when taken out of water," palpitation and tinnitus. The latter two symptoms no doubt occur also with great frequency at relatively low levels. It is clear, we think, that flying sickness is not comparable in the strict sense with mountain sickness, in spite of the fact that some of the symptoms are more or less identical. Hitherto we have had little direct evidence of what occurs as the result of rapid transference from high to low altitudes, for the laborious ascent of the mountaineer into rarefied air is very different from a speedy return to normal pressures, while the climb of a flying machine is hardly so rapid as to cause any ill effect. The pilot who is lifted from his machine, after a fast *vol plané*, in a semi-conscious condition, falling thereafter into a deep sleep, shows a phenomenon not met with either in mountain sickness or in caisson disease. Nevertheless we believe that some light may be thrown on this by another consideration. In his "Scrambles among the Alps" Whymper states that on one occasion he slipped and fell some 200 feet in seven or eight bounds. Curious as it may appear, though conscious at first, he "was like a patient under chloroform and experienced no pain," albeit badly cut about the head. The bounding through space did not feel disagreeable. He says that in his opinion in no very great distance more consciousness as well as sensation would have been lost, and on this he bases his view that "death by a fall from a great height is as painless an end as can be experienced." In a recent number of a weekly contemporary an interesting note was given on the facts connected with parachute descents of other days, and it was stated that on one occasion, after reaching an altitude of over 12,000 feet in a balloon, the parachutist launched out, but fell at once many hundreds of feet before his parachute opened. It appears that as a result of his rush downwards through space he practically lost consciousness, holding on automatically and regaining his senses an appreciable time after the parachute had attained its normal rate of descent. Evidently there are effects on the functions of the nervous system which are attributable to very rapid descent through space, from low to higher air pressures, no doubt, but in which the alteration of pressure is probably only one factor, and that, perhaps, not the most important. These phenomena are likely to be less rare now than formerly, and they open up a fascinating subject for study, one in which, as in caisson disease, we may hope that exact methods of scientific investigation and control will eventually lead to work becoming safe that was once dangerous, and to the extension of the limits hitherto set to its scope.

THE HEALTH OF THE JAPANESE NAVY

THE total strength of the personnel of the Imperial Japanese Navy (officers excepted) in 1913, the latest year for which statistics have been issued, was 46,890, being a decrease of 635, as compared with the strength in 1912. The *ratio of cases of sickness*, that is, of admissions to hospital, was 682.2 per 1000, this being an improvement on the figure for 1912, which was 716.6, and a still greater improvement on the average of 16 years, which was 804.2 per 1000. In our own navy the ratio of admissions averaged 656.6 for the five-year period 1908–1912. The average *number* of men daily in hospital has been 22.34 per 1000, compared with the similar figure of 26.97 for the quinquennium in the British Navy. The mortality ratio of the Japanese sailor has been 3.33 per 1000 and the invaliding ratio 16.64 per 1000; the former figure is a most satisfactory reduction on the ratio for 1912 which was 4 92, and on the 16 year average, which was 5 16 per 1000, but the invaliding shows an increase on the average for 1912, which was 15 15, this in its turn being an increase over the 16 year average, which was 14 88 per 1000 Possibly the examination is more strict now than in former years In addition to the in patients in hospital, 29 1 per 1000 of the strength have been under treatment out of hospital, practically the same as in the year preceding (29 98), but a considerable reduction on the 16 year average of 35 2 Among infectious diseases by far the greatest number of admissions were from venereal complaints, of these, there were 3541 cases Paratyphoid fever comes next with 562 admissions for the A variety, and 160 for paratyphoid B, of true typhoid there were 102 cases Except for malaria (248 admissions) and dysentery (140) there was no prevalence of any communicable disease, beri beri caused only 88 admissions In addition to 4423 conscripts, there were 23,399 volunteers for the Imperial Navy, of these, 9769 passed the medical examination, but 12,717 failed, 933 were prevented from attending by unavoidable circumstances The large excess of failures over passes points either to defective physique in the class from which recruits are drawn, or to a very stringent requirement on the part of the examining authority Our own naval statistics do not give the proportion of rejections among recruits, but for the army this proportion has averaged only 321 per 1000 We may, however, be quite sure that the Imperial Japanese Government know what they are about in maintaining a high standard of physical development for the recruit, and if circumstances arise to call for their intervention in the present conflict, we have the greatest confidence in the skill and courage of the personnel, and in the completeness of the organisation and preparedness for action of the Japanese forces, both naval and military

THE SUPERVISION OF THE PRACTICE OF MIDWIVES

IN a letter on certain grievances of midwives, printed in another column, a correspondent calls attention to two matters of direct interest to midwives and affecting less immediately a section of the general public The facts stated by "Fair Play' speak for themselves With regard to the first question to which he refers, the notifying to medical officers of health or to maternity centres the names of patients who engage midwives for coming confinements we are disposed to look upon the matter from the point of view of the medical profession, and to ask ourselves what would be the attitude of medical men to a proposal to inflict such an obligation upon them We conceive that it would be entirely hostile, and that the argument that it would "cut at professional confidence would be strenuously urged in opposition to it The practice of midwives is rightly subjected to supervision not imposed where medical men are concerned, but it is desirable that when regulations and provisions for official inspection are introduced they should commend themselves as necessary and should have as little as possible the appearance of being directed against a particular class Birth registration the notification of births and the notification of infectious disease are provided for upon public grounds and without regard to the social or financial position of those in respect of whom notice is given Notification of a prospective birth if enforced by law upon midwives would be an obligation affecting exclusively women of the class that engages midwives, and its advantages might well be outweighed by the resentment or apprehension that it would evoke as "class legislation" On the other hand, we conceive that there is little to prevent an antenatal notification once declared desirable in the case of midwives being made to apply where medical men are engaged, if merely for the sake of uniformity and to prevent any outcry against "class legislation. Such an innovation would surely need considerable evidence of its desirability before it commended itself to the medical profession The second matter touched upon by "Fair Play' only concerns the choice of the authority to exercise control over lying in houses, and we are in accord with his opinion, which we understand to be that in the metropolis uniform administration by the London County Council is preferable to the independent efforts of borough councils working in contiguous areas and inspired by varying degrees of zeal and intelligence Those best acquainted with the work done by the London County Council and the metropolitan borough councils would probably agree that the former is the best suited to exercise with firmness and discretion, and at the same time with uniformity, the duties referred to in "Fair Play's' letter Probably also the London County Council is the best qualified as a central authority to perform the task with economy, without sacrificing efficiency Rigid economy where the expenditure of money is concerned will be absolutely necessary for public bodies, as well as for individuals, for many years to come

ACUTE PHARYNGITIS ASSOCIATED WITH ERYSIPELAS

A CASE of the very rare conjunction of acute pharyngitis with erysipelas which is of both clinical and pathological interest, is recorded by Dr H S Muckleston in the *Canadian Medical Association Journal* for November, 1915 On March 21st 1914, Dr Muckleston saw in consultation a man who had been taken ill on the 17th with what was regarded as an attack of influenza Pain in the throat and dysphagia began on the 20th He complained of pain in swallowing, extreme dryness of the throat, and a feeling of something that blocked the passage Speech was so difficult that he preferred to reply to questions in writing The tongue was dry and blackened the soft palate and anterior pillars of the fauces were swollen and deeply congested The palate was dry and ridged with strings of mucus adhering to it The uvula was swollen to the size of the little finger with scattered petechiæ and a large bulla near the tip The tonsils were congested The posterior pillars of the fauces were swollen and deeply reddened the swelling extending down the sides of the pharynx to the level of the epiglottis Except for moderate congestion and slight rounding of the epiglottis the larynx was free Some scarification of the uvula and the use of a 10 per cent solution of cocaine gave marked relief and swallowing became easier In the evening the patient suddenly became deaf and there was a discharge from the right ear These symptoms were found to be due to hæmorrhagic bullæ on the meatal wall One had burst and the other was punctured and when the meatus was cleared out the membrane was seen to be of normal lustre but slightly injected There was [illegible] swelling of the auricle On the next day there were pronounced redness and swelling of the auricle and cheek, but the pharyngitis continued to improve The inflammation of the skin spread to the scalp, across the head, and down the right side of the neck to the shoulder and arm There were hyperpyrexia and for some days delirium, but ultimately recovery took place Reiche and Schomerus have reported a series of 31 cases of pneumococcic infection of the throat, in two of which erysipelas developed In one case a woman, in the last month of pregnancy, developed pneumococcic pharyngitis with dyspnœa. Labour began on the second day and was completed on the third, when erysipelas began The child died when 3 days old and the mother died two days later Pneumococci were found in cultures from bullæ of the skin in the larynx, the tonsils (here in company with streptococci), and the blood of the child Delavan has reported three cases of erysipelas of the pharynx or larynx with facial involvement, the redness beginning at the lips or nose Dr Muckleston suggests that in his case the path of infection of the skin was through the retropharyngeal and deep cervical glands Though the streptococcus is accepted as the usual microbe of erysipelas, the power of the pneumococcus to set up what is clinically the same condition has been shown In the cases in which the period of onset of the erysipelas is reported this was either the third or the fifth day of the pharyngitis However, Cornil published 50 years ago 18 cases, in half of which the erysipelas was primary and in the remainder secondary Of the 9 cases of extension from without inwards, 7 were fatal, while in the cases of the reverse 2 were fatal Delavan quotes Hippocrates, who says "When erysipelas extends from within outwards it is a favourable symptom, but when it removes from without to the internal surfaces it is a deadly one" In 1895 Sir Felix Semon read a paper at the Royal Medical and Chirurgical Society on "The Probable Identity of the Various Forms of Acute Septic Inflammations of the Throat and Neck hitherto described as Acute Œdema of the Larynx, Œdematous Laryngitis, Erysipelas of the Pharynx and Larynx, Phlegmon of the Pharynx and Larynx, and Angina Ludovici" However, in none of 14 cases reported by him do there appear to have been signs of erysipelas

OZÆNA AND THE ACCESSORY SINUSES OF THE NOSE

THE connexion between ozæna and inflammatory processes in the accessory sinuses of the nose has been much debated since 1873, when Michel very definitely restated the view that ozæna was secondary to chronic suppuration in these cavities This view has been more recently supported by numerous writers particularly Grünwald and is to the effect that both diagnosis and treatment should recognise the primary character of the septic processes in one or other of the accessory sinuses of the nose The opposite view however, is not without its supporters and Dr S Wetterstad now brings forward[1] his own extensive experience of the disease to prove that the involvement of these sinuses in ozæna is secondary when it does occur, and is often absent In the recent literature of ozæna he has found 16 cases in which careful post mortem examinations were made in 8 of these the accessory sinuses of the nose were normal, in 8 inflamed Examining over 1100 records of obduction in cases of all sorts, he finds that one or more of these sinuses showed signs of inflammation in no less than 31 per cent of the patients Hence, he argues, it is likely that the connexion between ozæna and infection of the nasal sinuses is commonly accidental, and the infection itself often a terminal event in cases where it does occur He also points out the difficulty of understanding how it is that an atrophic process like ozæna can be set up by infection from an inflamed nasal accessory sinus in view of the fact that such infections are common and habitually do give rise to hypertrophic inflammations of the nasal mucosa Again, he considers that the hereditary and familial character of ozæna is in favour of its primary nature, and he emphasises the importance of careful examination of every member of an ozæna family with the construction of the family tree, giving two such trees of his own investigation The second of these, embracing four generations and 40 individuals, comprises 9 cases of ozæna and 12 of atrophic rhinitis, with a negative Wassermann reaction in the three generations in which it was examined Finally, Dr Wetterstad states that he has long been on the look out for a case of inflammation of a nasal sinus leading to ozæna, but has never yet met with one On the other hand, in 8 out of 88 patients observed by himself he has seen ozæna lead to a secondary infection of one or more of the accessory sinuses He also considers it possible that both are due to a single process, sinusitis ozænosa, producing a fluid secretion in the accessory cavities of the nose infected, but a dry, crusted, and offensive secretion from the nasal mucous membrane

EFFECTIVE AND INEFFECTIVE INSECTICIDES

SOME interesting experiments have been undertaken by Professor Aldo Castellani, on service in the military hospitals at Uskub, Serbia, and Dr Thomas W Jackson, acting director of the American Red Cross Sanitary Commission in the same city, as to the efficacy or worthlessness of substances used as insecticides Their conclusions will prove of practical value to all concerned with hospital management and the care of crowded wards or institutions In regard to solid and liquid insecticides the substances which they have found to be deleterious to body lice are in the order of their efficiency kerosene, vaseline, guaiacol, anise preparations iodoform, lysol cyllin and allied preparations, carbolic acid solutions, naphthalene, and camphor Pyrethrum, according to these investigators, has a very feeble action on lice, while boric acid, sulphur, corrosive sublimate and zinc sulphate, when used in powder form, have apparently no action whatever As regards bed bugs kerosene, they think, is the best insecticide Next to it comes guaiacol, one of the most active substances they have tried Substances which are powerful licecides may have according to their experience, very little or no action upon bed bugs and vice versa. Iodoform, for example, kills lice within 10 to 15 minutes, but it has practically no deleterious action on bed bugs which may live for more than 24 hours when exposed to it Iodoform has also very little effect on fleas On the other hand, pyrethrum has a much more powerful action on bed bugs than on lice In the opinion of the investigators the best insecticide powder for use against lice on a large scale, as among troops and prisoners, is naphthalene This substance, they state, has a lower licecide action than kerosene, guaiacol, iodoform, and anise preparations, but it has a less displeasing odour than the first three named and is cheap In stored blankets and clothing it is also of considerable use, as frequently lice are found upon the blankets *laid by throughout* the summer Naphthalene is further *useful for* its well known deterrent action upon moths The *investigators* finally suggest that for the better class of patients a *menthol powder* is to be preferred to naphthalene *in practice*, as its odour is not displeasing, while it *is repellant* to *mosquitoes*, as well as to lice and fleas It is further pointed out that such a powder is *especially* useful in summer and in hot countries, as it has a cooling effect on the skin and often prevents prickly heat[1]

ANTHRAX IN THE SHAVING BRUSH

A SOMEWHAT disturbing account of some cases of anthrax in man traceable to infected shaving brushes appears in our columns this week Suspicion fell upon a shaving brush in the first instance because at the post mortem examination *it was noted that the small local* lesion came well within the individual s shaving area which covered a larger ground than usual The clue was *followed up and the brush was bacteriologically examined*, with the result that it could be definitely stated that it was infected with anthrax Further inquiry showed that other shaving brushes were grossly infected Subsequent experiments showed that the infection could be removed to a large extent by thorough washing but this process would not appear to give absolute security It is reassuring to learn that on the facts becoming known prompt action was taken to secure, so far as possible the withdrawal of the brushes from the market But the circumstances call for a very thorough inspection of the factories where these brushes were made and careful inquiry, no doubt, will follow as to the source of the infected hairs used for the purpose

THE BORDET-GENGOU REACTION IN ECHINOCOCCAL DISEASE

Dr L C Zapelloni has given in *Il Policlinico* for 1915 (Surgical Section) (Nos 7, 8 9, 10, and 11) the results of his investigations over a period of five years on the fixation of the complement in all the cases of echinococcal infection admitted into the Umberto I Hospital and of many of those occurring in the other hospitals at Rome He also gives an extensive analysis of researches in the same field of study and reported in the literature of the subject during the years 1906 to 1914 and the results of the control experiments made by himself The number of cases examined for diagnostic purposes and prior to any operative interference was 60 of those examined subsequently 54 and of those free from echinococcal disease 167 In addition there were in the cases reported by others about 550 in the first group about 200 in the second and more than 1600 in the third These large numbers afford ample material for estimating the fundamental points of practical and theoretical value of the reaction The details of the test are described minutely by the author, and the reactions showed that there *exist* in the blood of patients suffering from this disease specific antibodies of the amboceptor *type, and they* constitute one of the most satisfactory clinical *applications* of the *Bordet* Gengou principle The *reaction* was, *in fact* positive in 93 per cent of the cases examined as a means of diagnosis, whether the echinococcus was of the hydatidosus or multilocularis variety whether the parasites were living or dead in whatever organs they were situated and whether the serum was taken during life or after death The test also proved *of* value in showing the amount of antibodies present in the serum examined, and in this respect it is interesting to notice that the amount varied not in relation to the size of the hydatid cyst but rather with the conditions which facilitated or hindered the passage from the cyst into the circulation of substances with antigenic properties In fact, such conditions as calcification of the pericyst and prolonged suppuration existed in those cases which gave a negative reaction (7 per cent) As regards specificity the reaction was always negative when hydatid infection was absent, even cases affected with closely allied *taenia* responded negatively Moreover, in 0 25 per cent of reported cases where the reaction was falsely positive the result may be referred to some possible error of technique or to a real infection which was clinically inappreciable Immediately after operation *the reaction* was *more intensely positive* but the hydatid antibodies disappeared after one to two weeks or more After six months the reaction was usually negative The practical value of the test is the more evident when compared with the results of others such as eosinophilia and precipito reaction the *former being present in only* 60 per cent of the cases

At the next meeting of the Surgical Section of the Royal Society of Medicine on Feb 2nd at 5 30 P M, Dr F Hernaman Johnson will read a paper on the *Use of Condensers* and the Diagnosis Prognosis and Treatment of Nerve Lesions and give a demonstration

The next meeting of the Medical Society of London will be held on Monday Jan 17th when a discussion on "Gunshot Wounds of the Chest will be introduced by Colonel Sir John Rose Bradford F R S R A M C and Captain H Morriston Davies R A M C Lieutenant Colonel Hale White R A M C and others will take part in the discussion Fellows and others desirous of taking part in the discussion are requested to communicate with the honorary secretaries or the registrar 11 Chandos street W

SANITATION IN BILLETS AND CAMPS

BY ADAM WHITE, M B , CH B , D T M & H EDIN , D P H. CAMB ,
LIEUTENANT R.A.M C (T) OFFICER COMMANDING SANITARY SECTION 2 1ST NORTH MIDLAND DIVISION

BILLETS

As the billeting of troops is a matter which brings the civil and military authorities into specially close relationship and as considerable bodies of soldiers are liable to be quartered in billets from time to time the subject of the sanitary supervision of such abodes requires the earnest consideration of those charged with the conservation of the public health in general

The practice of billeting troops in private houses is a very ancient one, and references to it are found in petitions to the Crown in the Tudor and Stuart periods, in the Petition of Right (1628), and in the Bill of Rights (1689) To come to more modern times, the Army Act of 1909 provided that in the event of the Territorial Force being called up, the Crown should have power by the promulgation of an Order in Council, to declare that a state of emergency had arisen necessitating extensive billeting operations The relative Order in Council was made on August 4th, 1914

In pursuance of this Order any general or field officer in any part of the United Kingdom may issue a billeting demand upon the civil authority of the district in which he desires to have troops billeted In practice these operations are generally initiated through the agency of the police Occupiers of licensed premises, of public buildings and private dwelling houses, of warehouses, barns, and stables, as well as owners of unoccupied premises, are liable to provide billets But it is expressely enacted that the convenience of the various persons liable must be considered, and any person who believes himself aggrieved may have recourse to a court of summary jurisdiction

Varieties of Billets Accommodation in Various Areas

Speaking generally, we may say that there are three varieties of billet, viz. —

1 The soldier is provided with lodging, attendance, light (the specified illuminant being candles), fires, suitable utensils for cooking his rations, and also with sundries such as salt, &c Rations in kind are provided by the military authorities, or a money allowance in lieu of rations is issued to the soldier who then buys his own food The price paid for this form of billet is 9*d* for one soldier and 6*d* for each additional soldier It is found in practice that all cooking is done for the soldier by the housewife, although it is not incumbent upon her to undertake this duty Perhaps her well recognised readiness to play the role of cook may be explained in part by the chances of material gain which will accrue and in part by a quite understandable desire to save herself the trouble of cleaning up her kitchen after its use by those who have little experience in the culinary art

2 The soldier is provided with lodging &c and [illegible] meals The price for lodging and attendance is the same as that specified above, the meals [illegible] paid for according to a tariff

3 In this form of billet the men are put up in [illegible] houses and other buildings and it is [illegible] roof which is provided For this bare accommodation the sum of 1*d* per night per man is paid

The number of troops which a given area can accommodate or absorb is generally calculated as being so many per unit of population, but naturally the actual figure varies much with the character of the houses in the area and according to the economic status of the inhabitants and the industries which they carry on In addition, the presence or absence of absolute or relative overcrowding has an important bearing upon the subject It is generally held that billets with subsistence can be provided for a period of one week in the proportion of two soldiers to one of population, but in areas which have been war swept subsistence will be specially difficult to obtain Billets without subsistence can as a rule, be obtained in the case of rich agricultural districts on a basis of 10 men per inhabitant, and in the case of good class industrial towns on a basis of five to six men per unit of population As the density of population increases, the absorbing capacity naturally diminishes, and the figures quoted will be found to be impossible in areas in which the population is closely aggregated and in which a poor class of house is the rule

Sanitation in Billets

So far as sanitation is concerned, the two varieties of billet first named may be considered together When placed in these billets the soldier is living under somewhat similar general conditions to those obtaining in the case of the ordinary lodger or boarder, and he will be subjected to the same risks and vicissitudes There is a general tendency to overcrowd billets This is due partly to a desire on the part of the men to be with their friends and partly to the wish of the commanding officer to keep his personnel together as much as possible It is essential that this tendency should be counteracted, and it may be stated that 40 square feet of floor space should be regarded as a minimum in the sleeping room Taking the effective height of the room as being 8 feet, the above allowance of floor space will give a cubic allowance of 300 odd feet On account of the modesty of this requirement of air space it is essential that the rooms occupied should be well ventilated, and for this reason no rooms in which the windows do not open at least at the top and to a sufficient extent should be used for billeting purposes

As it is in the best interest of all concerned to conserve the health of the troops, every possible discretion should be exercised by those responsible for the selection of billets Information regarding houses which for any reason are unsuitable for the reception of soldiers should be obtained from the civil authorities or from the responsible officers of divisions which have previously occupied the area, and such houses should be sedulously avoided Houses which already have their full complement of inhabitants houses in which cases of infectious disease exist, houses the inhabitants of which are notoriously uncleanly or otherwise undesirable, and houses in which the general sanitation is below par come within this category

In the case of the third named variety of billet the conditions met with are altogether unusual in that the men are placed in domiciles which are totally unfurnished and which were intended to house a number of inmates much less than the number of soldiers placed in them for billeting purposes For example, we may have a house which under ordinary circumstances would be called upon to contain 10 or 12 persons used for the purpose of billeting 30 or 40 soldiers In such a case as this a severe strain is placed upon the kitchen, lavatory, and water closet accommodation

Although the commander of every unit is responsible to superior authority for the sanitary condition of any area which his unit may occupy, and although officers are enjoined to visit the billets of their men at irregular intervals at least once by day and once by night, it is highly desirable that all houses used as billets should be systematically inspected and supervised by the officer commanding the Divisional Sanitary Section As soldiers when living in billets are in more intimate domestic relationship with the civil population than is the case in other methods of quartering, it is of great importance that the local medical officer of health should have opportunities afforded to him for exercising his general public health functions In connexion with the inspection and supervision of billets we may now briefly consider some of the more important points which demand attention

Inspection and Supervision of Billets

General cleanliness of billets is absolutely essential for the prevention of disease and for the maintenance of military discipline Great care should be taken to ensure that the premises are kept thoroughly clean and tidy All bedding should be taken out and exposed to the fresh air at least every other day, and precautions should be taken to ensure the earliest possible detection of verminous infestation The rooms occupied, if uncarpeted, should be scrubbed twice per week, and oftener when the weather is wet The men themselves should undertake this work

When making inspections attention should be paid to the state of the cooking utensils, as their condition is a useful index of the general condition of the household in the matter of domestic cleanliness In addition the available cooking facilities and the accommodation provided for the storage of food demand attention Generally speaking, the cooking arrangements are quite satisfactory in the majority of houses, but it is unfortunately the case that the same reassuring statement cannot be made with reference to the food stores of the average house

When men are receiving their rations in kind (which is the most common method of rationing adopted) it is seldom that more than one day's rations are issued at once so that there is no great amount of food on the premises at any one time But even admitting that this is true, it is undoubtedly the case that when three or four men are billeted in the average four roomed occupied house, or when 30 or 40 men are quartered in an empty house the larder accommodation is severely taxed In both cases great care should be taken to see that the available food storage space is used to the greatest possible advantage, and that miscellaneous domestic articles are not allowed to encroach upon a part of the house which is not intended for their reception In the case of the empty house billet something may be done to ensure proper housing of the meat by the provision of improvised meat safes These can be readily constructed from wooden bars and fly proof wire gauze

Disposal of Garbage

The provisions for garbage removal should be carefully inspected In many small towns suitable receptacles are not provided and the refuse is not removed at sufficiently frequent intervals These defects should be remedied as far as possible

The latter condition (that of insufficiently frequent removal) can generally be overcome by methods adopted in consultation with the medical officer of health Nuisance is specially apt to arise from this cause in the case of empty houses which are being used for billeting purposes, as the domestic refuse resulting from the feeding and housing of 40 or 50 men is considerable The difficulty may be rendered somewhat less pressing by teaching the cooks to burn as much of the refuse as the kitchen fire will deal with

While it is not always possible to have the ideal type of refuse receptacle installed, and while it may in many cases be necessary to put up with makeshifts and to improvise from materials which lie to one's hand, an endeavour should be made to have the receptacles of suitable size and shape watertight, and covered

The refuse should be removed at least once every other day, and in the case of the empty house variety of billet the collection should be made every day In small townships with primitive methods of scavenging such regular and frequent collection is sometimes difficult to obtain, but regular and frequent removal should be aimed at and in all possible cases daily removal should be realised Failing efficient scavenging arrangements all garbage should be burnt in some form of incinerator erected in the garden or yard of the house This, of course, cannot be done in densely populated areas but in such areas it is generally not required

Disposal of Excreta

The congregating together in one house of a comparatively large number of men raises difficulties with regard to the disposal of fæces and urine One, or at most two water closets form the complement of the average house, and this provision is often not sufficient when the house is being occupied as a billet Additional accommodation must be provided, and the exact form which this added accommodation will take must vary in different cases

Additional water closets cannot, as a rule be provided and even if it were possible to provide such it is doubtful if this form of closet is the best for the purpose in view for we must remember that the occupation is in all probability to be purely temporary, and moreover a water closet provides temptations for its use as a means of getting rid of materials which it is not in the ordinary course of events, intended to deal with As a rule it may be said that anything in the nature of the conventional earth closet is not a success when this form of convenience is to be used by soldiers

Undoubtedly the best form which this additional accommodation can take is that of a bucket latrine The exact method of working bucket latrines will be discussed later in the remarks relating to camp sanitation Suffice it for the present to say that they should be provided on a scale of 10 per cent of strength The best results are obtained when the buckets are placed in some form of small shed constructed in the garden of the house Most large empty houses which are used for billeting purposes have comparatively large gardens so that little difficulty is experienced in this matter but it may be laid down as a general rule that a house which is deficient in water closet provision and which does not possess sufficient curtilage to accommodate a proper latrine shed should not be used for billeting troops

(To be continued)

MEDICINE AND THE LAW

Inquests and the Time Question

An inquest was held recently at Hurstpierpoint upon the body of an elderly lady who, having broken one of her thigh bones by falling in her room on Oct 11th, died on Dec 15th It was stated that the deceased made favourable progress until the middle of November when senile changes began to show themselves followed by death, as mentioned above At the inquest, no doubt quite properly held the coroner was asked within what period after an accident or injury to which a death might be traced it was necessary to hold an inquest His reply was to the effect that there was no limit, and that the fact that no one could be charged with murder or manslaughter more than a year and a day after the occurrence causing the death had nothing to do with the situation adding that he did not think he would hold an inquest if death occurred 20 years after an accident In this last observation we concur, for it would be waste of time and money to hold an inquiry which could have no result in any case so far as the perpetrator of any wrongful act was concerned and which would be unlikely to lead to any definite result of any kind. In most cases the year and a-day limit will be sufficient and the coroner upon such occasions might in his discretion, and unless there were any cogent reasons for holding an inquest decide that the evidence pointing to an "unnatural" death was not sufficient to necessitate an inquiry He would, of course be governed by circumstances by the medical evidence at his disposal, and by the consideration of possible facts rendering an inquest desirable upon public grounds Inquests are generally repugnant to the feelings of surviving relatives and although we have no definite statistics in support of our opinion we believe that coroners do at times exercise a discretion such as we have suggested We cannot for example, believe that a coroner in Cumberland would hold an inquest and bring up witnesses from Cornwall because he was told that the death of a person whose body lay within his jurisdiction was probably accelerated by an accident which the deceased met with in the latter county several years before death actually took place The law may be as stated by the coroner at Hurstpierpoint and may enable an inquest to be held after any lapse of time but we question the necessity for such a course in the public interest except on very rare occasions when the year and a day limit has been exceeded We might also suggest that if such inquests are seldom or never held it is because although the medical evidence might reasonably attribute death to an accident after a considerable time, such a death would not be in the ordinary acceptation of the term an "unnatural" one It certainly would not be a violent death however it was caused It is the safest course for a medical practitioner to report a case which has been under his care when the responsibility rests upon the shoulders of the coroner We refer to occasions where the medical man is satisfied that but for an accident or some such cause his patient would have been alive and medical evidence to that effect can be given

Poor Law Guardians and Vaccination

In Ireland the duty of enforcing the vaccination laws devolves on the boards of guardians and for the past few years as the result of an antivaccination campaign some of the boards have been deliberately avoiding their obligation in the matter As a result the proportion of primary vaccinations to births has fallen in the past ten years from nearly 90 per cent to 65 per cent The Local Government Board has not contented itself with issuing occasional circulars but recently recognising the dangerous conditions that were arising through neglect of vaccination the Board has shown its determination to compel boards of guardians to carry out the law and a few days ago application was made to the King's Bench to make absolute a conditional order of mandamus against the Letterkenny guardians The Lord Chief Justice in the course of his judgment said that the subject of compulsory vaccination came formally before the guardians [illegible] on June 23rd 1913 when a resolution was [illegible] that the matter of vaccination be left an open one [illegible] in case of non vaccination The affidavit of the clerk said that the guardians were informed that they were the final and ultimate tribunal to decide as to the enforcement of the provisions of the Vaccination Acts within their union Whether they were so or not it was for the court now to decide Section 10 of the Act of 1879 provided "that the guardians of any union in Ireland may direct proceedings to be instituted for the purpose of enforcing obedience to the provisions of the Vaccination (Ireland) Acts" The first question for the court was whether Section 10 was or was not mandatory in its operation It provided, it was true, that the guardians "may" direct proceedings to be instituted, and the guardians contended that this language gave them a discretion in the matter But it was settled law that provisions in a statute, though of a permissive character, might impose a duty His lordship cited some cases in support of this canon of construction with the view of showing it was well established and could not now be questioned. His lordship was clearly of opinion that the tenth section of the Act of 1879 was mandatory in its character, and that it was the duty of the guardians—a duty which could be enforced by mandamus—to take steps to enforce the compulsory provisions of the Vaccination Acts within their district His lordship came further to the conclusion that the Local Government Board had a locus standi to interfere where the guardians were not carrying out their duties under the Vaccination Acts, and that it was a proper relator in this proceeding The conditional order for a writ of mandamus should, therefore be made absolute His lordship added, with regard to the question of costs, that as this was the first occasion upon which it had been decided in Ireland that the duty of enforcing the Vaccination Acts was mandatory upon the boards of guardians, and as the Letterkenny guardians appeared to have adopted the course they did in the *bona fide* belief that they legally had a discretion in the matter, he did not think that they ought to be required to pay the costs personally "But" added his lordship "I should like it to be understood that for the future, if the order of the court in the present case stands guardians who persistently refuse to enforce the Vaccination Acts within their districts will do so at the peril of being obliged personally to pay the costs of proceedings to compel them to discharge their duty in this respect" Mr Justice Madden and Mr Justice Boyd concurred

The Second Conviction of an Impostor

Charged under the name of H J Herring, a person without medical qualifications was sentenced to four years penal servitude at a recent sessions of the Central Criminal Court for feloniously giving death certificates in four cases He was also indicted for bigamy The prisoner had personated Mr E Ken Herring a medical man practising in New South Wales, and having represented himself to be Mr E K Herring to a medical agency in London obtained the post of locum tenens during the absence of Mr W J Deighan upon war service Among the patients whom he attended four died and the prisoner signed the certificates of the cause of death He afterwards was for a time locum tenens to a medical practitioner at Cambridge and was arrested while acting in a similar capacity in Lancashire where he had been in two posts as locum tenens He had given death certificates in at least 12 instances besides those mentioned above Inquiry by the police had shown that several years ago he had been sentenced to penal servitude for five years for manslaughter having on that occasion represented himself to be Mr J B Hoffmeister a medical man who in fact was practising in the Isle of Wight He had acted as an assistant to druggists and having been married in 1906 and become the father of four children had gone through the ceremony of marriage with a second woman in 1910 perfectly well knowing that his wife, with whom he was in communication was alive The war affords an exceptional opportunity to dangerous imposters of this class but the fate of this particular scoundrel should be a warning to others Discovery and punishment usually supervene and nine years of penal servitude must weigh heavily against brief periods of success the comparative ease of which must be marred by dread of detection and arrest

THE ROYAL DENTAL HOSPITAL, Leicester-square W C has received a donation of £2000 from the trustees of the late Miss Hawker Smith

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

The undermentioned have been granted commissions as Surgeons for temporary service in His Majesty's Fleet —John Duffin (dated Dec 14th) Harry Forrest Stephen (dated Dec 17th) Hubert Musgrave Oddy (dated Dec 18th) Arthur Campbell Brown and Francis Temple Grey (dated Dec 21st) *James Bertie Simpson* and George William Marshall Findlay (dated Dec 22nd) Denys Maveson Percival Whitcombe (dated Dec 23rd)

ARMY MEDICAL SERVICE

Major (*temporary Lieutenant Colonel*) John C Bell relinquishes his temporary rank on vacating the appointment of *Assistant Director of Medical Services* (dated Nov 18th)

Temporary Colonel George L Gulland relinquishes his *commission* (dated Dec 11th)

ROYAL ARMY MEDICAL CORPS

Temporary Lieutenant Colonel Sir Ronald Ross K C B, relinquishes his commission (dated Nov 29th)

Lieutenant Colonel D Macaulay, South African Medical Corps, to be temporary *Lieutenant Colonel* (dated August 11th)

Major Sir Edward S Worthington, C M G M V O to be temporary Lieutenant Colonel whilst Commandant Officers' *Convalescent Home, Cimiez* (dated Nov 1st)

John Charles Grant Ledingham to be temporary Lieutenant Colonel (dated Dec 8th)

Major H Hemsted, South African Medical Corps *to be* temporary Major (dated August 13th)

The undermentioned to be temporary Captains —

Dated Dec 1st Frederick William Twort, Hugh Dickie, Thomas Gillman Moorhead and temporary Captain *George Beley, from the York and Lancaster Regiment*

The undermentioned temporary Lieutenants to be *temporary Captains* —

Dated August 15th William L G Davies

Dated Sept 10th William W Deans

Dated Sept 26th Ernest R G Greville

Dated Oct 1st *David Thomson*

Dated Oct 2nd John R P Allin

Dated Oct 3rd *Geoffrey Hadfield*

Dated Oct 5th *James H* Aikman and William C Jardine

Dated Oct 7th William H Laslett and Malcolm A MacDonald

Dated Oct 10th Thomas Fehily Mark Bates James A Glover, Norbert *Reader*, Wilfred A Macaskie George Jackson, Edgar A Pearson William J Nisbet, and Michael J Murray

Dated Oct 11th Frederick W McMillan

Dated Oct 12th Trevor O Williams

Dated Oct 19th John F Cox

Dated Oct 21st Charles F Kelly David W Reid, Charles H *Thompson*, and Richard Williams

Dated Oct 22nd Trevor R Snelling

Dated Oct 24th Roland R Wettenhall

Dated Oct 28th Martin W Littlewood

Dated Nov 11th John I Russell

Dated Nov 17th John B Fisher

Dated Nov 23rd Basil C Ashton

Dated Nov 24th Crawford Lundie and Walter Amslen

Dated Nov 25th *Frederick* Buick McCarter

Dated Nov 27th Charles A Kenny

Dated Dec 3rd Norman F *Hallows*

Dated Dec 21st Alexander Gibson Cyril Wace and Eric Bellingham Smith

Dated Dec 22nd L W Gemmell

The undermentioned to be temporary Lieutenants —

Dated Oct 14th *James Roberts Boyd*

Dated Nov 15th John Anderson

Dated Nov 27th Edward Sutcliffe John Fansworth Owen David Baker Mawson William Bannerman Harold Pace Gibb Gerald Francis Bird and Cyril Henry Edwards

Dated Nov 28th Cuthbert Edmund Arnold Hedley

Dated Nov 29th Robert Blackie Austin William Ernest Hills Joseph Scott Taggart Thomas Evans David McMurray Dickson and Robert Anderson

Dated Nov 30th Robert Henry Sherard Ian Fraser [illegible] Mackenzie and William Farber

Dated Dec 1st William Bligh James Foster Craik Thomas Christopher *Harley* Robert James [illegible] Neville Henry [illegible] John Farquhar MacLeod Thomas Harley Oliver [illegible] [illegible] William [illegible] Michael [illegible] [illegible] [illegible] Henry [illegible] [illegible] [illegible] [illegible] James William [illegible] Walter [illegible] Jam[illegible]

Dated Dec 2nd William Bow Tannahill Kent *Pretty, John Ross* and Oswald Vincent Burrows

The undermentioned relinquish their temporary honorary commissions on ceasing *to be employed with* No 7 British Red Cross (Allied Forces Base) Hospital —Dated Dec 7th Lieutenant Colonel W I Miles and Major H H Gill and Captains R G Murray, A F Forester J S Burn and J I Adler

Temporary Honorary Lieutenant B G *Klein* having ceased to be employed with the Welsh Hospital Netley relinquishes his commission

The undermentioned relinquish their commissions —

Dated Nov 8th Temporary Captain Guy A C [illegible]

Dated Nov 24th Temporary Lieutenant [illegible] Matheson

Dated Dec 2nd Temporary Captain William F [illegible]

The undermentioned temporary Lieutenants relinquish their commissions —

Dated Oct 24th David H Collingham

Dated Nov 17th Bernard Francis

Dated Dec 7th Andrew B Douglas

Dated Dec 13th Ninian F M Home Hay (on account *of ill health*)

Dated Dec 22nd *John Hegarty*

Temporary Lieutenant Joseph Brewer is placed temporarily on retired pay on account of ill health (dated Nov 18th)

The undermentioned to be temporary Honorary Lieutenants —

Dated Nov 29th Philip Hever Wells and Eric Go[illegible] Dingley

Dated Dec 1st John Nissen Deacon

Dated Dec 6th George Charles Berg and Charles H Colclough Byrne

Dated Dec 8th Lancelot George Jacob and Sam[illegible] Reginald Prall

Dated Dec 9th William Thomas

Henry Adrian Fitzroy Wilson to be temporary Honorary Lieutenant whilst serving with the British Red Cross Hospital Netley (dated Dec 25th)

Temporary Honorary Lieutenant James P [illegible] having ceased to serve with the British Red Cross Hospital Netley relinquishes his commission (dated Dec 6th)

Overseas Contingents (Canadian Army Medical Corps) [illegible] Ferguson to be temporary Captain (dated Dec 19th)

The undermentioned Lieutenants of the Canadian Army Medical Corps to be temporary Lieutenants —

Dated Nov 23rd Ralph Thomson McLaren [illegible] Hiram Freeman Ernest Samuel Moorhead Alex [illegible] Roberts James Bryce Brown Charles Stuart [illegible] Harry Whittaker Paddell Ernest Lomnel James D[illegible] Shields Archibald Forbes Laird and William Laurie Evans

TERRITORIAL FORCE

Royal Army Medical Corps

South Midland Mounted Brigade Field Ambulance [illegible] Lieutenant Frank Smith to be Captain

Highland Field Ambulance To be Captain [illegible] Benjamin F Alcock and Lieutenant John G [illegible]

Home Counties Field Ambulance To be [illegible] Captain Joseph [illegible] from [illegible] and Lieutenant Millward [illegible] Hay[illegible]

Lowland Field Ambulance [illegible] to be Captain

South Midland Field Ambulance [illegible] James Max[illegible]

[illegible]

South Western Mounted Brigade Field Ambulance Lieutenant John H Cumming to be Captain James Woodman Astley Cooper to be Lieutenant

Southern General Hospital Lieutenant Aubrey Radford to be Captain To be Lieutenants Thomas Sidney Stafford (late temporary Lieutenant R A M C) and Allan Nathaniel Worsley Major R L Rutherford resigns his commission on account of ill health

West Lancashire Field Ambulance The undermentioned Lieutenants to be Captains James P Thierens and William F Young To be Lieutenants Albert Victor Glendenning and Alan Hargrave Pinder

West Lancashire Casualty Clearing Station Duncan Francis Hunter to be Lieutenant

South Midland Casualty Clearing Station Guy Hannah Kirby to be Lieutenant

Western General Hospital Lieutenant Frank Chadwick to be Captain

London Sanitary Company Douglas Porter to be Lieutenant

East Anglian Field Ambulance Lieutenant Saville J Fielding to be Captain

East Lancashire Field Ambulance To be Lieutenants Charles Wainwright Fort and Arthur William Berry

Eastern General Hospital Lieutenant Ernest F Ballard to be Captain

Highland Casualty Clearing Station To be Captains Lieutenant John Alexander Innes and Lieutenant John Dow

Supernumerary for Service with the Officers Training Corps Lieutenant John P Kinloch to be temporary Captain whilst serving with the Aberdeen University Contingent Senior Division, Officers Training Corps

Attached to Units other than Medical Units—To be Captains Lieutenant George J E Trotter and Lieutenant Gerald Stephen Hughes To be Lieutenants James Burnet Smith and James Morrison Orr

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN the 96 largest English and Welsh towns with populations exceeding 50 000 persons at the last Census, 6950 births and 5462 deaths were registered during the week ended Saturday Dec 18th 1915 The annual rate of mortality in these towns, which had been 16 7 18·5 and 17 1 per 1000 in the three preceding weeks fell in the week under notice to 15 7 per 1000 of their aggregate population estimated at 18 136 180 persons at the middle of 1914 During the first 11 weeks of last quarter the mean annual death rate in these towns averaged 15·4, against a corresponding rate of 16 1 per 1000 in London. The annual death rate for the week under review ranged from 5 1 in Edmonton 6 6 in Coventry 6·9 in Swindon and 8 1 in Willesden and in Swansea to 20·0 in Liverpool 20 1 in Dudley and Blackpool 20·6 in Bootle, 21·5 in Sunderland, and 21 7 in Leicester

The 5462 deaths from all causes were 492 fewer than the number in the previous week and included 298 which were referred to the principal epidemic diseases, against numbers declining from 373 to 335 in the three preceding weeks Of these 298 deaths 75 resulted from measles, 68 from infantile diarrhœal diseases 65 from diphtheria 60 from whooping-cough 19 from scarlet fever, and 11 from enteric fever but not one from small pox. The mean annual death rate from these diseases did not exceed 0·9 or 0·1 per 1000 less than in the previous week The deaths attributed to measles, which had been 70 93 and 81 in the three preceding weeks fell to 75 and caused the highest annual death rates of 1 1 in Bristol 1 3 in Grimsby and in Swansea 1 8 in Bury 1·9 in Burnley 2·0 in Swindon 3 8 in Leicester and 4 1 in Gloucester The deaths of infants (under 2 years) from diarrhœa and enteritis which had been 125 [illegible] and 103 in the three preceding weeks fell to 65 and included [illegible] in London 6 in Manchester and 5 each in Birmingham and Leicester The fatal cases of diphtheria which had been 72 62 and 74 in the three preceding weeks fell to 65 of which 25 were registered in London and 3 each in [illegible] Trent and [illegible] The deaths attributed to whooping-cough which had been 57 63 and 47 in the three preceding weeks rose to 60 [illegible] deaths [illegible] in London 6 each in Liverpool and West Ham and 3 each in Birmingham Manchester and [illegible] The deaths referred to scarlet fever which had been 3 20 and 2 in the three preceding weeks fell to 19 and included 5 in London and 3 in [illegible] The fatal cases of enteric fever which had been 15 [illegible] in the three preceding weeks were again 11 of which [illegible] in London

[illegible] scarlet fever patients under treatment in [illegible] London Fever [illegible] seven preceding weeks, further fell to 2582 on Dec 18th 245 new cases were admitted during the week, against 318, 278, and 282 in the three preceding weeks These hospitals also contained on the date mentioned 1550 cases of diphtheria, 53 of enteric fever, 25 of measles, and 10 of whooping-cough, but not one of small pox. The 1416 deaths from all causes in London were 132 fewer than the number in the previous week, and corresponded to an annual death rate of 16 3 per 1000 The deaths referred to diseases of the respiratory system, which had been 398, 516, and 438 in the three preceding weeks, further declined to 357 in the week under notice, but were 44 in excess of the number registered in the corresponding week of the previous year

Of the 5462 deaths from all causes in the 96 towns, 243 resulted from different forms of violence and 461 were the subject of coroners' inquests while 1521 occurred in public institutions The causes of 36, or 0·7 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull and in 71 other smaller towns Of the 36 uncertified causes, 9 were registered in Birmingham, 6 in Liverpool, and 2 each in Bootle, St Helens, Preston, and Gateshead

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of 1915 990 births and 888 deaths were registered during the week ended Saturday, Dec. 18th The annual rate of mortality in these towns, which had been 22 7, 22 4 and 18 7 per 1000 in the three preceding weeks, rose to 19 7 per 1000 in the week under notice During the first eleven weeks of last quarter the mean annual death rate in these towns averaged 18·0, against 15 4 per 1000 in the large English towns Among the several towns the death rate during the week ranged from 12 7 in Kilmarnock, 12·9 in Clydebank, and 13 8 in Motherwell, to 26 6 in Perth, 28·0 in Greenock and 28·9 in Falkirk

The 888 deaths from all causes were 47 in excess of the number in the previous week, and included 64 which were referred to the principal epidemic diseases, against 87 and 77 in the two preceding weeks Of these 64 deaths, 24 resulted from measles 14 from diphtheria 11 from scarlet fever, 8 from infantile diarrhœal diseases, and 7 from whooping-cough, but not one from enteric fever or from small pox. The mean annual death rate from these diseases was equal to 1 4, against 0·9 per 1000 in the large English towns The deaths attributed to measles, which had been 29 31 and 24 in the three preceding weeks were again 24 in the week under review, and included 6 each in Edinburgh and Greenock, and 5 each in Glasgow and Hamilton The deaths referred to diphtheria, which had been 15 21, and 19 in the three preceding weeks fell to 14 of which 4 occurred in Edinburgh 3 in Aberdeen and 2 each in Greenock and Kirkcaldy The fatal cases of scarlet fever which had been 15, 11 and 20 in the three preceding weeks, fell to 11, and included 6 in Glasgow and 3 in Aberdeen The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 15 17 and 12 in the three preceding weeks further declined to 8 of which 3 were registered in Glasgow The 7 deaths referred to whooping-cough were 4 in excess of the average in the earlier weeks of the quarter, and included 3 in Glasgow and 2 in Dundee

The deaths referred to diseases of the respiratory system, which had been 322 291 and 211 in the three preceding weeks, fell to 203 in the week under notice, but were 39 above the number registered in the corresponding week of the previous year The deaths from violence numbered 38, against 34 and 17 in the two preceding weeks

HEALTH OF IRISH TOWNS

In the 27 town districts of Ireland with an aggregate population estimated at 1 212,350 persons at the middle of 1915 505 births and 516 deaths were registered during the week ended Saturday, Dec 18th The annual rate of mortality in these towns which had been 20·1, 21 8 and 20·0 per 1000 in the three preceding weeks, rose to 22 2 per 1000 in the week under notice During the first eleven weeks of last quarter the mean annual death rate in these towns averaged 18 3 against corresponding rates of 15 4 and 18·0 per 1000 in the English and Scotch towns respectively The annual death rate for the week mentioned was equal to 24·9 in Dublin (against 16 3 in London and 19 1 in Glasgow) 20·0 in Belfast 23 8 in Cork 21·5 in Londonderry 8 5 in Limerick and 22 8 in Waterford while in the 21 smaller towns the mean death rate was 17 3 per 1000

The 516 deaths from all causes were 52 in excess of the number in the previous week and included [illegible] which were referred to the principal epidemic diseases, against 50 and 37 in the two preceding weeks Of these 46 deaths 18 resulted from measles, 10 from infantile diarrhœal diseases, 8 from whooping-cough, 7 from scarlet fever 2 from enteric fever, and 1 from diphtheria but not one from small pox The mean annual death rate from these diseases was equal to 2·0, against corresponding rates of 0·9 and 1 4 per 1000 in the English and Scotch towns respectively The deaths attributed to measles, which had been 10 15 and 14 in the three preceding weeks, rose to 18, of which 11 were registered in Dublin and 7 in Belfast The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 17 12, and 9 in the three preceding weeks were 10 in the week under review, and included 8 in Dublin The fatal cases of whooping-cough which had been 9 11, and 5 in the three preceding weeks, rose to 8, and comprised 4 in Belfast 3 in Dublin, and 1 in Drogheda The deaths attributed to scarlet fever, which had been 10 7 and 4 in the three preceding weeks, rose to 7, of which 4 occurred in Belfast and 3 in Dublin The fatal cases of enteric fever were registered in Dublin and Londonderry and that of diphtheria in Belfast

The deaths referred to diseases of the respiratory system which had been 117, 144, and 122 in the three preceding weeks, were 121 in the week under notice Of the 516 deaths from all causes, 142, or 28 per cent, occurred in public institutions and 11 resulted from violence The causes of 19, or 3 7 per cent of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest, in the large English towns the proportion of uncertified causes did not exceed 0 7 per cent

THE PLACE OF PROSTHETICS IN THE DENTAL CURRICULUM

To the Editor of THE LANCET

SIR,—The General Medical Council s inquiry into the causes of an alleged shortage of dental surgeons has perforce opened up questions as to whether the present curriculum and examination requirements need modification In your annotation in THE LANCET of Dec 4th, 1915, and some cognate remarks in earlier issues you pointedly recognise the fact that an overhauling and tuning up of the educational machine is desirable on other grounds than merely those of an alleged shortage of skilled working hands or the scaring and other damage done by piratical craft You state that the work required of the future dentist "will be more of the character of dental surgery than dental mechanics, and that the curriculum should be amended in accordance The difficulty of properly fitting into a scheme of dental education the plebeian subject of dental "mechanics or prosthetics is hardened by the fact that in all other specialties in medicine instruction or direct interest in the making of appliances has long ago been abandoned and handed over to separate and distinct classes of operatives The construction of dentures is retained in the curriculum as one of the required subjects of study and some plain facts justify this attitude of the authorities even if one excludes what has been done and requires doing in conditions arising out of the present war

My present object is to suggest that there are two directions in which one might look for a better harmonising of the time given to dental prosthetics with the total time period of the curriculum

1 If the results of reducing the former three year period of [illegible] training in prosthetics to two years should seem to justify a further reduction to one year a maintaining of the standard of proficiency reached can be made sure of only by a distinct improvement in the method or scheme of instruction The efficient construction and application of dentures is essentially based upon a knowledge of the forms and normal interactions of the natural teeth, as well as of the cheeks, lips and tongue and the pressure reactions of the oral tissues generally How was that knowledge acquired under the apprenticeship system? In the great majority of cases it was not adequately acquired at all, and in perhaps no case was the degree of knowledge gained anything like commensurate with the time spent—two years, and in many instances a minimum of three whole years The pupil was left to pick up his ideas of natural teeth from various assortments of porcelain teeth that the manufacturer certainly did not offer for pedagogical purposes And if a fortunate pupil here and there was encouraged to look into the natural mouth there was no pretence made of giving a course of instruction, systematic or other Judged by all reasonable tests, the dental schools have had better results from the same two year period of training But even in the schools further progress is damped down by the all pervading traditions of the older and still recognised system of private apprenticeship, under which the study of dental anatomy is not even begun until—*after* at least two years—the pupil is passed on to the hospital school as one fairly competent to construct and apply substitutes for lost natural teeth From a 12 years school experience as an instructor in the technical side of prosthetics, I have solid ground for believing that a systematised study of the relevant facts in morphology and dynamics should be entered upon from the beginning and go on concurrently with the technical exercises This alone should accelerate the student s real progress to an extent equivalent to a gain or saving of at least three to six months on the two years course A sound knowledge of surface anatomy should be insisted upon in any rational scheme of instruction in prosthetics, and the collateral value in all practical work of such an introduction to dental anatomy is quite obvious As the average student learns only those subjects that are scheduled and obligatory, maintenance of the present haphazard system amounts in effect to an actual withholding of knowledge and instruction

2 The practice of delegating the technical or extra oral part of prosthetics to mechanics who are outside the immediate control of dental surgeons is increasing This kind of delegation is justifiable only on the assumption that the dental surgeon is competent to design efficient dentures and to form accurate judgments upon any prosthetic work constructed for him If then, the mechanical training period is shortened on the plea that the dentist need not be an expert technician certain safeguards are called for in order to ensure good prosthetic service for the community To that end the student in prosthetics should have a much larger amount of clinical instruction and experience in which his competence and judgment upon all matters relating to the design and application of dentures would constantly be exercised and tested to the satisfaction of expert supervisors This clinical teaching could be carried as far into the full four years course as might be deemed advisable If on the other hand [illegible] such instruction is to be given by private [illegible] their pupils in private practice it is [illegible] right from all points of view that the pupil [illegible] enter a dental school should [illegible] by an examination There should be [illegible]

forward and a gathering in of loose ends in order that, in the strenuous days ahead, the dentists of this country may continue to hold their position as second to none

I am, Sir, yours faithfully,

D M SHAW,

Instructor and Curator of the Mechanical Laboratories Royal Dental Hospital of London

Leicester-square W C., Dec. 22th 1915

GERMAN MEASLES

To the Editor of THE LANCET

SIR,—Although the substitution of the title epidemic roseola or roserash for this disease, as suggested by Dr Clement Dukes in your issue for Dec 25th, might be desirable, I would suggest that until writers of text-books initiate the practice it is premature to expect the medical profession in general to adopt such a course

I am, Sir, yours faithfully,

Brighton Dec. 27th, 1915 C W HUTT, M D, D P H

A COMBINED PHYSICAL TREATMENT FOR DISABLED SOLDIERS

To the Editor of THE LANCET

SIR,—*Ex Africa semper aliquid novi* In your issue of Dec 25th a humorous letter is published from the East of Scotland Dr T D Luke, of Peebles, very modestly describes himself as "a humble balneologist, yet I venture to suggest that even the most humble balneologist usually knows that in neurasthenic conditions there is all the difference between the application of the ordinary douche and the under water douche or the running water bath I would suggest to Dr Luke that if he made inquiries of the medical authorities at the Grand Palais Hospital in Paris he will find that there is a similar difference between the ordinary hot douche and the hyperthermal *eau courante* treatment, against which he gibes so pleasantly

I am, Sir, yours faithfully,

J CAMPBELL McCLURE

Harley-street W Dec 2[illegible]th 1915

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND

THE WEEK'S SUBSCRIPTIONS

THE subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund received during the week have been as follows —

	£ s d		£ s d
Per [illegible] L D [illegible] [illegible] Dr C J [illegible]	0 3 6	Balance of Fund raised by medical men of Mansfield and neighbourhood to give [illegible] to a Belgian family who have now returned to Belgium (per Dr C [illegible])	8 1 2
Dr [illegible]	1 0 0	Dr [illegible]	0 10 6
[illegible]	5 0		
Dr G D H [illegible]	1 0 0		

Subscriptions to the Fund should be sent to the treasurer of the Fund Dr H A Des Voeux, at 13 Buckingham-gate London S W and should be made payable to the Belgian Doctors and Pharmacists Relief Fund crossed Lloyds Bank Limited

The War

THE CASUALTY LIST

THE following names of medical men appear among the casualties announced since our last issue —

Died of Wounds

Colonel E O Wight, R.A M C, Assistant Director of Medical Services, with the 49th division

Lieutenant O G Maginness, attached to the Royal Field Artillery, was educated at St Bartholomew's Hospital and received his qualification in 1913 Prior to the war he had an appointment in H.M Dockyard, Pembroke Docks

Wounded

Lieutenant J Campbell, R A M C

Lieutenant A C Edwards, R A M C, attached to the 4th Yorks Light Infantry (T F)

Lieutenant F G Foster, R A M C

Captain C A Bernard, R A.M C, attached to the 4th York and Lancaster Regiment (T F)

Captain J S Hall R A.M C, attached to the 5th York and Lancaster Regiment (T F)

Captain A L Shearwood R A M C

THE CENTRAL MEDICAL WAR COMMITTEE MEDICAL ENROLMENT

Compulsory military service need not affect the position of members of the medical profession, as the arrangements made by the Local Medical War Committees should suffice to meet all the demands of the medical service of the army Full details of the plan of the Scottish Medical Service Emergency Committee are given below, and the details of the method of procedure in England and Wales, which it is hoped to announce next week, will probably be on the same lines Medical men in England and Wales who have not yet enrolled should at once do so through the Local Medical War Committees, which are in direct communication with the Central Medical War Committee for England and Wales This Committee will give to each applicant a certificate of enrolment It has arranged the grouping of members, and with regard to the order in which individuals should be called on for service it will consider, in coöperation with the Local Medical War Committees, the special difficulties of any individual practitioner On any point of personal difficulty medical men in England and Wales are invited to communicate direct with the secretaries, 429, Strand, London, W C

The Central Medical War Committee has been actively engaged working at certain of the problems which have been lately discussed in Parliament and the daily press in connexion with the demands made by the War Office upon the members of the civilian medical profession As might have been expected, the principal difficulties arise in connexion with the position of the panel practitioners who are under contract to discharge certain duties, and upon whose services the National Health Insurance Commissioners naturally desire to exercise their lien Much detailed information is in the hands both of the Commissioners and the executive subcommittee of the Central Medical War Committee as to the number of general practitioners compared with population in the different administrative areas, and the result of coöperation will certainly smooth away some of the difficulties which are only too apparent These depend mainly upon the fact that the number of medical practitioners in industrial areas under the ordinary conditions of peace is no more than is reasonably necessary to carry on the average work of these areas Yet many of these practitioners have gone to the war, and more are urged to do so

SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE

This Committee has now set out a medical recruiting scheme for 1916 Some months ago, by desire of the various professional executives in Scotland, the Committee undertook the duty of bringing under the notice of practitioners the need of the army for more medical men At the request of the War Office the Committee agreed further to deal with applications by practitioners for commissions in the Royal Army Medical Corps The outlines of its policy, and the procedure which it was proposed to follow, were set out in a Memorandum of June 28th last, a copy of which was sent to all Scottish practitioners The plans so laid down, which were indicated in THE LANCET,[1] were carried out, and a satisfactory response was made by the profession to the calls upon them Since the period in question, however, there has come into being the general recruiting scheme promoted by Lord Derby, which has impressed all men of military age with an increasing sense of their obligations towards the country, and the Committee has been in consequence requested by the Director General of Army Medical Services, with the concurrence of Lord Derby, to continue and expand its work in such a manner as to form a link with the general arrangements of the recruiting scheme The statement of the Committee in view of the new circumstances runs as follows —

It is intended that the duty of dealing with members of the medical profession in Scotland, so far as the medical service of the army is concerned, shall subject to the instructions of the Director General, continue to be discharged by us, and we are authorised to state that medical men who have been approached by agents of local recruiting organisations on the ground that they are of military age under Lord Derby's scheme for the lay population, should apply to us for guidance

In drawing up a new scheme to meet these new conditions, we require in the first place to ascertain what service or services each practitioner resident in Scotland will be prepared to render if called upon The War Office has decided (1) that no man under 45 years of age will be employed as a commissioned officer in the Army Medical Service unless he undertakes general service obligations for a year, and is found to be physically fit for duty at home and abroad, and (2) that no man over 55 years of age will be accepted for home service In accordance with this decision practitioners are divided into three groups and the services appropriate to each group are noted in the following schedule —

Group	Age	Service
A	Under 45	Lieut R A M C (general service)
B	45 to 55	Lieut R A M C (home service) Part time home military work Locum tenens away from home (for practitioner absent on service) Part time home civil work (in carrying on practice or part of practice of neighbouring practitioner absent on service)
C	55 and upwards	Part time home military work Locum tenens away from home (for practitioner absent on service) Part time home civil work (in carrying on practice or part of practice of neighbouring practitioner absent on service)

As regards these services, attention is drawn to the enclosed registration form which should be filled in by all practitioners resident in Scotland who do not hold a commission in a branch of the Royal Army Medical Corps or in the Medical Department of the Navy As it is our duty not only to obtain applications for commissions but also to safeguard the interests of the general public by preventing undue depletion of any district, offers by practitioners to serve with the army or to act as whole time locum tenentes will be held as subject to the condition that arrangements can be made to have their present civil work carried on during their absence

In organising medical effort throughout Scotland generally we propose to act as heretofore in coöperation with the Local War Committees which we have recognised for each division of the British Medical Association When the results of our registration inquiry have been ascertained and collated we shall confer with these Local Committees and determine the number of practitioners who should be expected to go on service from each area The Local Committees acting on our instruction, will, after timeous notice, as occasion demands, call upon selected practitioners to give the service appropriate to their age group

In making a call for whole time military service the Local War Committee will issue to practitioners the Army Form of Application for a Commission in the Royal Army Medical Corps, and these forms when filled in should be returned to the secretary of the Local War Committee, and the subsequent arrangements should be made through him In making calls for other services the secretary of the Local War Committee will provide practitioners with all necessary information These calls which will be successive, will begin to be made in the month of January, 1916 Precise dates for calls succeeding the first cannot now be stated We shall, in instructing Local Committees be guided by our knowledge of the needs of the army as intimated to us from time to time by the Director General

This statement of the Committee concludes with an intimation that on any question of duty which may arise in consequence of such calls or otherwise, practitioners are at liberty to refer to the Committee as a body duly appointed and empowered to issue letters of excuse Notice to this effect can be given on a form which may be obtained from the secretary Questions of physical fitness or unfitness are expressly excluded from the province of the Committee These can be decided only by a Regular Officer of the Royal Army Medical Corps following an application for a commission as lieutenant Those found physically unfit should offer for one or more of the remaining services in the schedule

The statement is signed by A H F Barbour President of the Royal College of Physicians Edinburgh James Hodsdon President of the Royal College of Surgeons, Edinburgh Ebenezer Duncan President of the Royal Faculty of Physicians and Surgeons of Glasgow, J A Kynoch Dean of the Faculty of Medicine, University of St Andrews, T H Bryce Dean of the Faculty of Medicine University of Glasgow, Theodore Shennan, Dean of the Faculty of Medicine, University of Aberdeen Harvey Littlejohn Dean of the Faculty of Medicine Edinburgh University, John C McVail Deputy Chairman National Health Insurance Commission Scotland Robert Muir Professor of Pathology University of Glasgow T K Monro Regius Professor of the Practice of Medicine University of Glasgow J J Hamilton Chairman Scottish Committee British Medical Association, John Adams Vice chairman Scottish Committee British Medical Association John Playfair President of the Edinburgh Medical Guild John Gordon President Aberdeen Branch British Medical Association, John Stevens Secretary Edinburgh Branch British Medical Association J P Currie Medical Officer National Health Insurance Com mission, Scotland, Norman Walker, Direct Representative for Scotland on the General Medical Council (convener)

---

[1] THE LANCET, June [illegible] 1915, p [illegible]

The statement is accompanied by two forms One is to be filled in by practitioners not now holding a commission The other is directed to practitioners already holding a commission when the intimation form should be filled in, either by himself or by some person on his behalf. Either a registration or an intimation form—but not both—should be filled in in respect of each practitioner The appropriate forms, duly filled in, are being received by the secretary, Scottish Medical Service Emergency Committee, Royal College of Physicians, Edinburgh

WORK OF THE RED CROSS

The report of the joint finance committee of the British Red Cross Society and the Order of St John of Jerusalem has just been issued It is a document of which the country should be proud especially as the work it records has been accomplished mainly by voluntary helpers The report deals with the year which ended on Oct 20th, 1915, and shows how more than a million and a half of money has been used economically and beneficently on behalf of our sick and wounded Although for all practical purposes the work of the two societies began on the first day of the war it was not till Oct 20th, 1914, that the societies agreed to work hand in hand under a joint war committee, which during the 12 months under notice has spent £1,864,036 The expenses of management, excluding appeals, have amounted to only 1¼ per cent, or 2¾*d* in the £ on the whole income If the cost of appeals be added it makes the expenses of management 3½*d* in the £ It is interesting to note that on Oct 20th last year the societies had 697 motor ambulances at work, while the total number of vehicles in use was 1301 The following is a summary of the figures relating to the year's work —Hospital stores and comforts handled, £463 455 (cost of handling, 2 96 per cent), spent in France and Flanders (not including motor ambulances), £293,509 spent in Malta and Near East (mainly for Gallipoli) £194,812 spent in Serbia and Montenegro £43,846, spent on 'transport of wounded' (mainly motor ambulances), £615 963, number of motor ambulances, cars, kitchens, &c, at work 1301, spent on hospital trains, £48 097 spent on maintenance of British Red Cross Hospital Netley, £69,758 spent on St John Brigade Hospital Etaples £42 818 spent on King George Hospital Stamford street London £49 153, spent on Calais Enteric Hospital £17 643 spent on hospitals and convalescent homes in Egypt £25,604 spent on Australian Forces in Egypt, £21 054

We regret to record the death in Flanders on Dec 19th last of Colonel Ernest Octavius Wight, M R C S D P H Assistant Director of Medical Services who was killed by a shell while he was helping to extricate some of his motor ambulances from a dangerous position

---

GERMAN CASUALTIES —Mr Tennant stated in [illegible] to a question in the House of Commons [illegible] that the casualties [illegible] published in the official casualty [illegible] Saxony Bavaria and Württemberg up to [illegible] amounted to [illegible] Of the [illegible] 216 were killed or had died of wounds [illegible] 130 were prisoners [illegible] had died of disease and [illegible] were [illegible] These figures do not include the naval casualties

WAR SERVICE BADGES —An Army Council Order was issued on Dec 20th last stating the decision to issue armlets (1) to men who presented themselves for service in the army since the beginning of war and up to midnight on Dec 12th, but who were rejected on medical grounds, (2) to men who after midnight on Dec 12th presented themselves for immediate service with the colours and who were rejected on medical grounds Each class will be divided into two categories (*a*) Men who on examination have been certified as medically unfit on account of organic disease, and (*b*) men who have been rejected on account of eyesight or some slight physical defects The men in category (*a*) of each class will be registered, but those in category (*b*) of each class will be attested and passed to the Army Reserve In no case will an armlet be issued to men who are obviously unfit for service in the army, such as those who are totally blind, crippled, or paralytic

DUNDEE UNIVERSITY AND THE WAR.—The annual report of University College, Dundee, states that the war has caused a serious diminution of men students, and it seems that under the pressure which is now being exercised in recruiting none of the men undergraduates, save only those physically unfit or under military age, will be left The war has also seriously affected the finances, and the accounts closed with a deficit of £280 It was estimated that during the current year the fees would show a further reduction

ECONOMY IN BRAINS —The medical profession is not the only one which views with anxiety the waste of brains in the firing line At the conference of headmasters held at the Board of Education on Dec. 22nd and 23rd a resolution was unanimously carried affirming that—

> In the opinion of this conference very grave loss to the country is caused by the employment of young students of exceptional mathematical and scientific ability as subalterns in line battalions

Mr A L Francis M A, headmaster of Blundell's School, Tiverton, who moved the resolution, emphasised the fact that the present war being eminently a war of science, the place for the young man who had a special gift for science, mathematics or mechanics was in the laboratory

THE CRAIGLEITH HOSPITAL CHRONICLE —In the Christmas number Lieutenant Colonel Sir Joseph Fayrer gives some interesting figures of the number of men treated in Craigleith and the other military hospitals in Edinburgh up to and including Nov 23rd last The total number is 12,466 of which 10 564 were at Craigleith, 754 at the Royal Infirmary, 344 at the Deaconess Hospital 109 at the Leith Hospital and 694 at Dalmeny The numbers include men of the Expeditionary Mediterranean Home Service Canadian Australian Belgian, and South African Forces The Home Service furnished the largest number—8327 There were 67 Belgians 57 Canadians and 5 Australians

SERBIAN RELIEF FUND —Reports from Salonika continue to confirm the fact that such hospital staffs as were able to escape from Serbia are stranded there with no immediate opening for useful work. The French are arranging free transport to Ajaccio Corsica where a refugee camp has been established for 2000 Serbians and 4000 other refugees are expected in France This work for the expatriated Serbs takes the place for the present of definite hospital work The address of the Serbian Relief Fund is 5 Cromwell road S W

R A M C MEN IN TRAINING AT EASTBOURNE —The correspondent of the [illegible] Eastbourne gives an interesting account of the 3000 men who are at present training there They form about 6 per cent of the population of the town a proportion large enough to make itself felt and it is recorded of them that their exemplary behaviour renders their presence in the town a source of real pleasure The companies are drawn from all parts of England and there are a few recruits from Scotland Wales and Ireland The day's work begins at 6 55 A M with the roll-call Parades are held at 9 A M and 2 P M and there is a tattoo at 9 30 P M The first parade takes the form of squad drill Swedish drill stretcher drill lectures and route marches On the downs there are many opportunities of hill climbing and after a full morning's drill the men have been known to cover 15 or 16 miles in the afternoon The lectures given deal with such subjects as hygiene and physiology The apparent These depend mainly upon the fact that the number of medical practitioners in industrial areas under the ordinary conditions of peace is no more than is reasonably necessary to carry on the average work of these areas Yet many of these practitioners have gone to the war, and more are urged to do so

SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE

This Committee has now set out a medical recruiting scheme for 1916 Some months ago, by desire of the various professional executives in Scotland, the Committee undertook the duty of bringing under the notice of practitioners the need of the army for more medical men At the request of the War Office the Committee agreed further to deal with applications by practitioners for commissions in the Royal Army Medical Corps The outlines of its policy, and the procedure which it was proposed to follow, were set out in a Memorandum of June 28th last, a copy of which was sent to all Scottish practitioners The plans so laid down, which were indicated in THE LANCET,[1] were carried out, and a satisfactory response was made by the profession to the calls upon them Since the period in question, however, there has come into being the general recruiting scheme promoted by Lord Derby, which has impressed all men of military age with an increasing sense of their obligations towards the country, and the Committee has been in consequence requested by the Director General of Army Medical Services, with the concurrence of Lord Derby, to continue and expand its work in such a manner as to form a link with the general arrangements of the recruiting scheme The statement of the Committee in view of the new circumstances runs as follows —

It is intended that the duty of dealing with members of the medical profession in Scotland, so far as the medical service of the army is concerned shall, subject to the instructions of the Director General continue to be discharged by us and we are authorised to state that medical men who have been approached by agents of local recruiting organisations on the ground that they are of military age under Lord Derby's scheme for the lay population, should apply to us for guidance

In drawing up a new scheme to meet these new conditions, we require in the first place to ascertain what service or services each practitioner resident in Scotland will be prepared to render if called upon The War Office has decided (1) that no man under 45 years of age will be employed as a commissioned officer in the Army Medical Service unless he undertakes general service obligations for a year, and is found to be physically fit for duty at home and abroad , and (2) that no man over 55 years of age will be accepted for home service In accordance with this decision practitioners are divided into three groups and the services appropriate to each group are noted in the following schedule —

Group.	Age	Service
A	Under 45	Lieut. R A M C (*general service*)
B	45 to 55	Lieut R A.M C (*home service*) Part time home military work Locum tenens away from home (for practitioner absent on service) Part-time home civil work (in carrying on practice or part of practice of neighbouring practitioner absent on service)
C	55 and upwards	Part time home military work Locum tenens away from home (for practitioner absent on service) Part time home civil work (in carrying on practice or part of practice of neighbouring practitioner absent on service)

As regards these services, attention is drawn to the enclosed registration form, which should be filled in by all practitioners resident in Scotland who do not hold a commission in a branch of the Royal Army Medical Corps or in the Medical Department of the Navy As it is our duty not only to obtain applications for commissions, but also to safeguard the interests of the general public by preventing undue depletion of any district, offers by practitioners to serve with the army or to act as whole-time locum tenentes will be held as subject to the condition that arrangements can be made to have their present civil work carried on during their absence

In organising medical effort throughout Scotland generally, we propose to act as heretofore in coöperation with the Local War Committees which we have recognised for each division of the British Medical Association When the results of our registration inquiry have been ascertained and collated we shall confer with these Local Committees and determine the number of practitioners who should be expected to go on service from each area. The Local Committees acting on our instruction, will, after timeous notice, as occasion demands, call upon selected practitioners to give the service appropriate to their age group

In making a call for whole-time military service, the Local War Committee will issue to practitioners the Army Form of Application for a Commission in the Royal Army Medical Corps, and these forms when filled in, should be returned to the secretary of the Local War Committee, and the subsequent arrangements should be made through him In making calls for other services the secretary of the Local War Committee will provide practitioners with all necessary information These calls, which will be successive will begin to be made in the month of January, 1916 Precise dates for calls succeeding the first cannot now be stated We shall, in instructing Local Committees be guided by our knowledge of the needs of the army as intimated to us from time to time by the Director General

This statement of the Committee concludes with an intimation that on any question of duty which may arise in consequence of such calls or otherwise, practitioners are at liberty to refer to the Committee as a body duly appointed and empowered to issue letters of excuse Notice to this effect can be given on a form which may be obtained from the secretary Questions of physical fitness or unfitness are expressly excluded from the province of the Committee These can be decided only by a Regular Officer of the Royal Army Medical Corps following an application for a commission as lieutenant Those found physically unfit should offer for one or more of the remaining services in the schedule

The statement is signed by A H F Barbour, President of the Royal College of Physicians, Edinburgh , James Hodsdon, President of the Royal College of Surgeons, Edinburgh , Ebenezer Duncan, President of the Royal Faculty of Physicians and Surgeons of Glasgow , J A Kynoch, Dean of the Faculty of Medicine, University of St Andrews , T H Bryce Dean of the Faculty of Medicine, University of Glasgow , Theodore Shennan, Dean of the Faculty of Medicine, University of Aberdeen , Harvey Littlejohn, Dean of the Faculty of Medicine, Edinburgh University , John C M'Vail, Deputy Chairman, National Health Insurance Commission Scotland , Robert Muir Professor of Pathology, University of Glasgow, T K. DIPLOMA IN PUBLIC HEALTH

Part I and II —Ra[illegible] Edulji Dastur

THE LEEUWENHOEK MEDAL —Professor H A Lorentz, president of the Dutch Academy, writing to congratulate Surgeon General Sir David Bruce, A M S adds that Leeuwenhoek was a foreign member of the Royal Society and the greater part of his discoveries were first published in the Philosophical Transactions The award is made every ten years and this is the first made to a British scientist the previous laureates being Ehrenberg (1875) Ferdinand Cohn (1885) Louis Pasteur (1895) and Beyerinck (1905)

LEBANON HOSPITAL FOR MENTAL DISEASES —This hospital is situated at Asfuriyeh near Beyrout, Syria, and was founded in 1900 by the late Mr Theophilus Waldmeier Owing to the war the seventh annual report is somewhat belated in its appearance but it shows a record of excellent work For the year ending March 31st 1915 55 men and 31 women were admitted to the hospital. If to this number is added 109 patients who remained in the hospital on March 31st, 1914 the total number of patients cared for in the hospital during the year is 195 The financial report shows a slight increase of receipts from subscriptions though the payments from friends of patients show a fall of £353 The general health of the hospital throughout the year has been good. At the present moment, owing to the war provisions of all kinds are exceptionally high in price while patients are unable to contribute to their maintenance but the work of the hospital is still being carried on under the able direction of Dr H Watson Smith and an English matron As it is impossible to send money direct from London to Beyrout the financial affairs of the hospital are managed for the present by the American Presbyterian Board

MEDICAL SICKNESS AND ACCIDENT SOCIETY —A meeting of this society was held on Dec 17th 1915 at 300 High Holborn Dr F J Allen being in the chair The reports submitted showed that during the month of November the claims for sickness had risen slightly above expectation but that for the whole year so far the total experience was below the total expectation In spite of the congestion of business generally owing to the war it was reported that new proposals received were greater in number than those for the same period in the preceding year The number of additional proposals received had been fairly well maintained. One [illegible] feature noted was the increase in the combined sickness and accident and life assurance contracts issued and the tendency among existing members to avail themselves of the opportunity of increasing their insurances [illegible] the addition of endowment life assurances payable at the age of 60 or previous death The number of claims from members on military service had fortunately been few in comparison with the total number who were serving in the Royal Army Medical Corps and similar forces [illegible] of this item will probably be included [illegible] the next annual general meeting [illegible] The [illegible] avail themselves of the society's insurance against sickness and accident, and any desirous of so doing can obtain all information and a prospectus on application to the Secretary, Medical Sickness and Accident Society, 300 High Holborn.

PRESENTATION TO MR H G BARLING —At a gathering on Dec 22nd, presided over by the Lord Mayor of Birmingham, a presentation was made to Mr H Gilbert Barling, F R C S, Vice chancellor of the University of Birmingham on the occasion of severing his active connexion with the Birmingham General Hospital after 36 years service The presentation took the form of an illuminated address and his portrait in oil colour to be hung in the board room

THE LEAGUE OF MERCY —The annual meeting of the League of Mercy was held at St James s Palace on Dec. 21st, 1915 when Lord Farquhar, who presided read a letter from the King s private secretary in which their Majesties rejoiced that during the 17 years of the League s existence it had distributed no less than a quarter of a million sterling to the hospitals in and around London. Sir Frederick Green the treasurer, said the total income for the year was £19 582, an increase of £6[illegible]2 over the previous year A sum of £14 000 had been given to King Edward s Hospital Fund The list of district totals was headed by Westminster with £1832 more than last year, South Kensington followed with an increase of £1150 Sir William Collins, referring to the rise in the cost of hospital necessities owing to the war said that quinine had gone up from *8d* per ounce to *5s 6d* while aspirin had advanced from *2s* to *48s*, and atropine had gone up by enormous leaps During the meeting Prince Alexander of Teck bestowed the Order of Mercy upon a number of ladies and gentlemen

DEATH OF A VETERAN PHYSICIAN —John Rimington Fothergill M D St And died at his home in Darlington on Dec. 13th in his ninety first year He was the senior magistrate of the borough and was for many years honorary physician to the local hospital He was a great-great nephew of John Fothergill of London, physician and Quaker philanthropist who died in 1780, and his father was John Fothergill M R C S, who left his native Wensleydale to practise in Darlington about 100 years ago John Rimington Fothergill was born just when the world s first passenger train began to run between Darlington and Stockton in 1825 After studying in Edinburgh he joined his father in 1848 and in that year they used chloroform in a case of puerperal eclampsia—probably the first application of anæsthesia to this condition Thirty years later he retired from active practice but continued to act as a consulting physician for another 20 years Dr Fothergill took an active part in the civic philanthropic, and political life of his town remaining a strong Liberal to the end A keen fox hunter in his earlier days he continued to catch salmon in the river Tees until arthritis lamed him when he was about 75

The Establishment of the Army

The House of Commons has authorised an addition of 1,000,000 men to the land forces of the Crown, bringing the establishment up to 4,000,000

Midwives (Scotland) Act

The Midwives (Scotland) Act received the Royal assent on Thursday, Dec 23rd

The Christmas Recess

Parliament has risen for a short Christmas recess The House of Commons will resume on Tuesday, Jan 4th During the debate on the adjournment for the holidays, various points relating to the recruitment of the Royal Army Medical Corps and to the details of its administration were raised Mr TENNANT, the Under Secretary for War, replied to the discussion on these matters

---

HOUSE OF COMMONS

MONDAY, DEC 20TH

German and Austrian Medical Men

Commander BELLAIRS asked the Under Secretary for Foreign Affairs how many German and Austrian doctors and so-called German and Austrian Red Cross employees had been allowed to go through our naval blockade under safe conducts to Europe and how many under instructions from the Foreign Office without safe conduct, and what equivalent was obtained from Germany in the number of British subjects released—Lord ROBERT CECIL replied The number of such persons given safe conducts is 86 and the number of those who were to be allowed to pass without safe conducts is 69 I am not aware of the precise number in each category who may have been arrested on the way owing to suspicion of fraud, but the number is not large With regard to the last part of the question, His Majesty's Government have not so far felt obliged to refuse requests made to them on the ground of the Geneva Convention for the free passage of enemy doctors and Red Cross employees returning to their own country from overseas In most cases doctors and Red Cross officials captured or detained by the Germans have been also released But as in some cases they have not done so, His Majesty's Government is considering the advisability of detaining similar German individuals who would otherwise be returned

Hospital Units in the Balkans

Mr ALDEN asked the Under Secretary for Foreign Affairs whether he was able to make any statement regarding the present position of the various hospital units from England and Scotland that had been compelled to leave Serbia —Lord ROBERT CECIL answered Sir Ralph Paget, who is acting for His Majesty's Government in this matter, has succeeded in collecting the members of the British units who had escaped from Serbia at San Giovanni di Medua, from where it is hoped to transport them to Italy Till transport is provided, which I hope will be very shortly, Sir Ralph Paget may be trusted to do all that is possible for the safety and comfort of the units under his charge

Recruits and Minor Physical Defects

Mr BOYTON asked the Financial Secretary to the War Office whether he was aware that a number of proposed recruits were rejected for minor physical defects, many of which could be successfully dealt with in general hospitals, and whether His Majesty's Government would consider the desirability of paying those who offered to undergo operations or treatment at army rates with dependent allowances whilst they were detained in hospital, provided that they had previously attested —Mr FORSTER replied The number of men rejected for physical defects of a kind which could be cured by surgical operations is inconsiderable, and the risk and disadvantages of the course suggested are so serious that I fear I cannot adopt it

Dentists with the Expeditionary Force

Answering Sir A MARKHAM, Mr TENNANT (Under Secretary for War) said There are 43 dentists employed with the Expeditionary Forces in France exclusive of those employed with the Canadian contingent

Uninoculated Officers

In reply to Mr ANDERSON, Mr TENNANT said A commanding officer of any unit would be within his rights and powers in preventing any uninoculated officer from proceeding on active service overseas, because such an officer may, if he contracts enteric fever, be a grave source of danger to his brother officers and the men under his command

Panel Practitioners in England

Sir E CORNWALL asked the representative of the National Insurance Commissioners what was the number of doctors now on the panel in London and in the provinces respectively as compared with the totals on July 1st 1914 —Mr C ROBERTS answered, The figures on July 1st, 1914, are not obtainable without a special return from Insurance Committees, but the figures for January, 1914 which would not differ materially from those of the following July were London, 1400, other English areas 14,600 (including doctors on more than one panel) The corresponding figures of doctors who will be on the panel for 1916 are approximately In London 1440, in other English areas 14,400 These figures include a number of medical men on military service whose names remain on the panel whilst some other doctor or doctors are undertaking to carry out their duties

TUESDAY, DEC 21ST

The Drug Tariff

Mr BOOTH asked the representative of the National Insurance Commissioners whether the Commissioners had asked the London Insurance Committee to administer the new drug tariff for 1916, whether the Committee on Thursday declined to receive a report that they should do so whether a special committee had been appointed to examine further the Commissioners' proposal, whether he could see his way to modify the scheme so as to avoid an increase of staff, and was he aware that it was estimated that at least £4000 additional yearly cost would fall upon London to carry out the larger part of the Commissioners' proposals —Mr C ROBERTS said, in reply The duty of pricing prescriptions has been transferred to Insurance Committees by regulations recently framed in accordance with the recommendations of the Departmental Committee on the Drug Tariff, and it is the statutory duty of Committees to make administrative provision for the purpose of calculating the payments due to chemists under the agreements already entered into for 1916 The Commissioners have been in communication with the Committee as to the arrangements necessitated by this duty which they understand are in course of preparation by the Committee. Committees have already been informed that special provision will be made for meeting any additional expenditure properly incurred by them on this work out of sums released in consequence of the new tariff arrangements Any such estimate as is suggested of the additional cost involved would appear, however, to be in excess of all reasonable anticipation

WEDNESDAY, DEC 22ND

First Eastern General Hospital

Sir F BANBURY asked the Under Secretary of State for War whether the kitchen arrangements in the First Eastern General Hospital were planned for 520 patients and whether they now had to provide for 1500 patients, whether the commandant of this hospital was in charge of two other institutions, and what salary did he receive —Mr TENNANT replied The facts are substantially as stated in the first part of the question The hospital has expanded and outgrown the original kitchen accommodation The question of improving the kitchen arrangements has been taken in hand, and I hope the defects will soon be remedied In the expansion two other section hospitals have been formed which are in the general charge of the commandant of the hospital and administered under him by officers commanding sections The commandant is a colonel in the Territorial Force, Army Medical Service, and draws the pay of his rank.

Medical Missions to Serbia

Mr MILLS asked the Secretary of State for Foreign Affairs whether any list of the doctors and nurses who had left Serbia had been received by His Majesty's Government, and, if so, whether such list would be published —Sir EDWARD GREY wrote in reply No list has been received Our latest information is that Sir Ralph Paget arrived at Brindisi on Dec 18th with 120 members of the medical missions to Serbia

Vaccination Acts in Dublin

Mr NUGENT asked the Chief Secretary to the Lord Lieutenant in Ireland whether he was aware that Dublin soldiers who were fighting in the trenches had recently been prosecuted and convicted in their absence as defaulters under the Vaccination (Ireland) Act, was he aware that if those soldiers had resided in Great Britain they would have been able to avoid the risk of such proceedings by making a declaration of conscientious objection to the vaccination of their children, and whether he will give instructions to boards of guardians in Ireland for the suspension of the issuing of summonses for non vaccination until such opportune time as the law on this subject should in Ireland be made similar to that which obtained in Great Britain and thus conform to the recommendations of the Royal Commission on Vaccination —Mr BIRRELL (in a written answer) replied Legal proceedings have recently been instituted in Dublin against defaulters under the Vaccination Acts The papers did not show whether the persons in default were civilians or whether any of them belonged to the army There are no exemptions from vaccination and it would

most unfair if children were not protected from small pox while their fathers were at the war As regards the latter part of the question, I would refer the honourable Member to a previous reply on the subject

THURSDAY, DEC 23RD

Epsom Asylum

Replying to Mr TYSON WILSON, Sir JOHN SIMON (the Home Secretary) said that owing to the paramount need for economy the Treasury had felt it their duty to object to a further loan for carrying out the contract for the erection of an asylum at Epsom Negotiations with the contractor were still pending He was informed that none of the blocks could be completed under 12 months apart from lighting, heating, and drainage The question of using them as hospitals for wounded soldiers had been considered by the Army Council but the Council did not think it necessary to complete the blocks for this purpose

Tuberculosis Treatment

Sir EDWIN CORNWALL asked the representative of the National Insurance Commissioners to state the amount contributed under the Act in respect of the treatment of tuberculosis cases in this country in the four years ending March, 1915 —Mr C ROBERTS wrote in reply Subject to some slight adjustment the amount available under Section 162 of the National Insurance Act 1911 in respect of the period July 15th 1912, to Dec 31st, 1914 for defraying the expenses of sanatorium benefit in the United Kingdom is £2,150 000 Further, a sanatorium benefit grant of £100 000 was voted in the supplementary estimates for 1914-15, £50,000 being paid into the special account for credit to the four National Health Insurance Funds and the balance being revoted in the estimates for 1915-16 I may add that these figures do not include sums of £125 000 £180 000, £480 000, and £385 000 voted in the estimates (original and supplementary) for 1913-14 and in the estimates for 1914-15 and 1915-16 respectively as provision for statutory grants under Section 17 of the National Insurance Act 1911, and for special grants towards the cost of schemes undertaken by local authorities or combinations of local authorities with the approval of the departments administering the grants for the treatment of tuberculosis generally

A Leprous German Prisoner

Mr BUTLER LLOYD asked the Under Secretary for War whether he was aware that a German prisoner of war, in an advanced condition of leprosy, had been kept for many months in spite of repeated remonstrances from the officer of the guard of the King s Shropshire Light Infantry, within a few paces of the sentry and guard room at Handsforth, near Manchester, and whether he would take immediate steps to have him removed to a more suitable locality —Mr TENNANT answered Special accommodation has been prepared for this prisoner of war at a hospital at Dartford and he is now being removed there

Mr F HARVEY Would it not be possible to make arrangements to send this prisoner back in the next party of exchanged prisoners?—Mr TENNANT I do not think that would be a good thing to do

Medical Men and Service in the Army

Mr PRINGLE asked the Prime Minister whether civilian doctors up to 45 years of age were being asked to join the Royal Army Medical Corps whether he was aware that doctors already in the service were in many cases performing routine and other duties which could be equally well performed by men who had not a medical qualification and if so whether arrangements would be made to relieve doctors in the service of such duties before further depleting the number of doctors available for the civilian population —Mr ASQUITH answered There is urgent need for qualified medical men due to wastage and the necessity for equipping new units My information does not support the allegation contained in the last part of the question

The Neglect of the Civil Population

On the motion for the adjournment for the Christmas recess

Mr PRINGLE called attention to the employment of medical men in the service of the army and the further drafts upon the civilian doctors which were being made at the present time The depletion of the supply of civilian doctors was becoming a serious matter for the whole civil population of the country and obviously a large number of further doctors would be required with the million men for the raising of whom the House had just granted authority He wanted to know whether the War Office was going to recruit medical men for the new forces on the same scale as they had been [illegible] for the army that had been raised and whether [illegible] were to be used as wastefully and [illegible] at [illegible] of the doctors who [illegible] He would only deal with certain [illegible] At the present time there were ambulances in this country all with a full complement of medical officers, and the great majority of those officers were doing practically no medical work At least their medical work was negligible in quantity The great majority of them had nothing to do but to attend to the feet of recruits That was a wasteful use of the services of skilled medical men These ambulances could be dealt with by a much smaller number of skilled medical men, and if the skilled medical men who were thus being uselessly employed were set free their services would be at the disposal of the civil population, or at least some of them could be withdrawn from their present units and employed for the purposes of the further million men who were to be raised Appeals were now being made in various parts of the country to civilian doctors He knew of one district in London where only ten days ago a meeting of all the medical men was called on behalf of the British Medical Association, and it was there intimated that it was the desire of the War Office that all medical men under 45 years of age should put their services at the disposal of the army If that was done there would be a famine of doctors for the civil population That was a situation which ought not to be allowed to come to pass It was not only in regard to the field ambulances in this country that he had to direct the attention of the Under Secretary for War There was a similar situation in regard to field ambulances abroad It was true that these field ambulances were extremely busy when attacks took place or when our forces had a push against the enemy, but at other times the medical officers attached to these ambulances were largely idle They had no employment With regard to base hospitals the situation was the same There were, in normal times far too many medical officers for the work which they had to do and when a period of hard pressure came the services of the medical men were needlessly taken up with clerical work and with surgical dressings, which could quite well be done by those who had no medical qualifications The sole work of medical men enlisted in the army should be to devote their energies and attention to the care of the sick and the wounded There were many other details upon which the medical organisation was open to criticism He was told on authority which he considered good that there were large numbers of specialists who were now being employed for ordinary medical work All these things constituted a case for inquiry and for reorganisation The large number of civilian doctors who had gone into the army did not take kindly to red tape methods The honourable Member also called attention to the fact that since the beginning of the war there had not been a single meeting of the Medical Advisory Committee

Mr TENNANT By design

Mr PRINGLE That is all the worse He did not believe that good results could be attained by consulting men singly

Clerical Work in the Royal Army Medical Corps

Mr DOUGLAS HALL said that he must endorse what the honourable Member had said about the uneconomic use of medical men at the front A great many surgeons out there never did anything but administrative work There were many medical men there highly qualified men, who never went near a patient and never went into the operating-room at all They were simply there as clerks to fill up endless forms and to administer the discipline of the orderlies He had been five months at the front and had had to do with a great many hospitals In every hospital there were one or two medical officers who spent nearly all their time in office work The W
Office might consider whether it would not be
allocate some of these duties to some officer who
got the high medical skill which officers of
Army Medical Corps possessed He thought
who went out to one of our large bases
at the number of doctors who at one
work at all while other places
doctors He did not know w
but it seemed to him that

Replying to Mr Tyson Wilson, Sir John Simon (the Home Secretary) said that owing to the paramount need for economy the Treasury had felt it their duty to object to a further loan for carrying out the contract for the erection of an asylum at Epsom Negotiations with the contractor were still pending He was informed that none of the blocks could be completed under 12 months apart from lighting, heating, and drainage The question of using them as hospitals for wounded soldiers had been considered by the Army Council but the Council did not think it necessary to complete the blocks for this purpose

Tuberculosis Treatment

Sir Edwin Cornwall asked the representative of the National Insurance Commissioners to state the amount contributed under the Act in respect of the treatment of tuberculosis cases in this country in the four years ending March, 1915 —Mr C Roberts wrote in reply Subject to some slight adjustment the amount available under Section 162 of the National Insurance Act 1911 in respect of the period July 15th, 1912, to Dec 31st, 1914, for defraying the expenses of sanatorium benefit in the United Kingdom is £2,150,000 Further, a sanatorium benefit grant of £100 000 was voted in the supplementary estimates for 1914-15, £50 000 being paid into the special account for credit to the four National Health Insurance Funds, and the balance being revoted in the estimates for 1915-16 I may add that these figures do not include sums of £125,000 £180,000, £480,000, and £385,000 voted in the estimates (original and supplementary) for 1913-14 and in the estimates for 1914-15 and 1915-16 respectively as provision for statutory grants under Section 17 of the National Insurance Act 1911, and for special grants towards the cost of schemes undertaken by local authorities or combinations of local authorities with the approval of the departments administering the grants for the treatment of tuberculosis generally

A Leprous German Prisoner

Mr Butler Lloyd asked the Under Secretary for War whether he was aware that a German prisoner of war, in an advanced condition of leprosy, had been kept for many months, in spite of repeated remonstrances from the officer of the guard of the King's Shropshire Light Infantry, within a few paces of the sentry and guard room at Handsforth, near Manchester, and whether he would take immediate steps to have him removed to a more suitable locality — Mr Tennant answered Special accommodation has been prepared for this prisoner of war at a hospital at Dartford and he is now being removed there

Mr E Harvey Would it not be possible to make arrangements to send this prisoner back in the next party of exchanged prisoners?—Mr Tennant I do not think that would be a good thing to do

Medical Men and Service in the Army

Mr Pringle asked the Prime Minister whether civilian doctors up to 45 years of age were being asked to join the Royal Army Medical Corps, whether he was aware that doctors already in the service were in many cases performing routine and other duties which could be equally well performed by men who had not a medical qualification and, if so, whether arrangements would be made to relieve doctors in the service of such duties before further depleting the number of doctors available for the civilian population — Mr Asquith answered There is urgent need for qualified medical men due to wastage and the necessity for equipping new units My information does not support the allegation contained in the last part of the question

The Needs of the Civil Population

On the motion for the adjournment for the Christmas recess,

Mr Pringle called attention to the employment of medical men in the service of the army and the further drafts upon the civilian doctors which were being made at the present time The depletion of the supply of civilian doctors was becoming a serious matter for the whole civil population and the country and obviously a large number of further doctors would be required with the million of men, for the raising of whom the House had just granted authority He wanted to know whether the War Office was going to recruit medical men for the new forces on the same scale as they had been recruited for the armies that had been raised, and whether their services were to be used as wastefully and as uneconomically as those of the doctors who were at present serving He would only deal with certain branches of the subject At the present time there were many field ambulances in this country all with a full complement of medical officers, and the great majority of those officers were doing practically no medical work At least their medical work was negligible in quantity The great majority of them had nothing to do but to attend to the feet of recruits That was a wasteful use of the services of skilled medical men These ambulances could be dealt with by a much smaller number of skilled medical men, and if the skilled medical men who were thus being uselessly employed were set free their services would be at the disposal of the civil population, or at least some of them could be withdrawn from their present units and employed for the purposes of the further million men who were to be raised Appeals were now being made in various parts of the country to civilian doctors He knew of one district in London where only ten days ago a meeting of all the medical men was called on behalf of the British Medical Association, and it was there intimated that it was the desire of the War Office that all medical men under 45 years of age should put their services at the disposal of the army If that was done there would be a famine of doctors for the civil population That was a situation which ought not to be allowed to come to pass It was not only in regard to the field ambulances in this country that he had to direct the attention of the Under Secretary for War There was a similar situation in regard to field ambulances abroad It was true that these field ambulances were extremely busy when attacks took place or when our forces had a push against the enemy, but at other times the medical officers attached to these ambulances were largely idle They had no employment With regard to base hospitals the situation was the same There were, in normal times, far too many medical officers for the work which they had to do, and when a period of hard pressure came the services of the medical men were needlessly taken up with clerical work and with surgical dressings, which could quite well be done by those who had no medical qualifications The sole work of medical men enlisted in the army should be to devote their energies and attention to the care of the sick and the wounded There were many other details upon which the medical organisation was open to criticism He was told on authority which he considered good that there were large numbers of specialists who were now being employed for ordinary medical work All these things constituted a case for inquiry and for reorganisation The large number of civilian doctors who had gone into the army did not take kindly to red tape methods The honourable Member also called attention to the fact that since the beginning of the war there had not been a single meeting of the Medical Advisory Committee

Mr Tennant By design

Mr Pringle That is all the worse He did not believe that good results could be attained by consulting men singly

Clerical Work in the Royal Army Medical Corps

Mr Douglas Hall said that he must endorse what the honourable Member had said about the uneconomic use of medical men at the front A great many surgeons out there never did anything but administrative work. There were many medical men there, highly qualified men, who never went near a patient and never went into the operating-room at all They were simply there as clerks to fill up endless forms and to administer the discipline of the orderlies He had been five months at the front and had had to do with a great many hospitals In every hospital there were one or two medical officers who spent nearly all their time in office work The War Office might consider whether it would not be possible to allocate some of these duties to some officer who had not got the high medical skill which officers of the Royal Army Medical Corps possessed He thought that anyone who went out to one of our large bases would be surprised at the number of doctors who at one time were doing no work at all, while other places were suffering for want of doctors He did not know whether that could be avoided, but it seemed to him that there might be some better system for distributing the medical men where they were wanted

The Government Reply

Mr Tennant (Under Secretary for War) replied In all the actions that have been taken by the medical authorities in the War Office in the administration of the medical services in the army there have been constant and continuous association and conference with the civil medical services of this country The closest touch has been kept with the civil medical profession, and when my honourable friend complains that the Medical Advisory Committee has not met I really must say once again that it seems a little absurd to criticise the War Office for not having had formal meetings of the Committee when the members of that Committee are meeting the authorities and those responsible for the administration of the medical services of the army day by day and almost hour by hour That does seem to me

The Establishment of the Army

The House of Commons has authorised an addition of 1,000,000 men to the land forces of the Crown, bringing the establishment up to 4,000,000

Midwives (Scotland) Act

The Midwives (Scotland) Act received the Royal assent on Thursday, Dec 23rd

The Christmas Recess

Parliament has risen for a short Christmas recess The House of Commons will resume on Tuesday, Jan 4th During the debate on the adjournment for the holidays, various points relating to the recruitment of the Royal Army Medical Corps and to the details of its administration were raised Mr TENNANT, the Under Secretary for War, replied to the discussion on these matters

---

HOUSE OF COMMONS

MONDAY, DEC 20TH

German and Austrian Medical Men

Commander BELLAIRS asked the Under Secretary for Foreign Affairs how many German and Austrian doctors and so-called German and Austrian Red Cross employees had been allowed to go through our naval blockade under safe conducts to Europe and how many under instructions from the Foreign Office without safe conduct, and what equivalent was obtained from Germany in the number of British subjects released—Lord ROBERT CECIL replied The number of such persons given safe conducts is 86 and the number of those who were to be allowed to pass without safe conducts is 69 I am not aware of the precise number in each category who may have been arrested on the way owing to suspicion of fraud, but the number is not large With regard to the last part of the question, His Majesty's Government have not so far felt obliged to refuse requests made to them on the ground of the Geneva Convention for the free passage of enemy doctors and Red Cross employees returning to their own country from overseas In most cases doctors and Red Cross officials captured or detained by the Germans have been also released But as in some cases they have not done so, His Majesty's Government is considering the advisability of detaining similar German individuals who would otherwise be returned

Hospital Units in the Balkans

Mr ALDEN asked the Under Secretary for Foreign Affairs whether he was able to make any statement regarding the present position of the various hospital units from England and Scotland that had been compelled to leave Serbia —Lord ROBERT CECIL answered Sir Ralph Paget, who is acting for His Majesty's Government in this matter, has succeeded in collecting the members of the British units who had escaped from Serbia at San Giovanni di Medua, from where it is hoped to transport them to Italy Till transport is provided, which I hope will be very shortly, Sir Ralph Paget may be trusted to do all that is possible for the safety and comfort of the units under his charge

Recruits aad Minor Physical Defects

Mr BOYTON asked the Financial Secretary to the War Office whether he was aware that a number of proposed recruits were rejected for minor physical defects, many of which could be successfully dealt with in general hospitals, and whether His Majesty's Government would consider the desirability of paying those who offered to undergo operations or treatment at army rates with dependent allowances whilst they were detained in hospital, provided that they had previously attested —Mr FORSTER replied The number of men rejected for physical defects of a kind which could be cured by surgical operations is inconsiderable, and the risk and disadvantages of the course suggested are so serious that I fear I cannot adopt it

Dentists with the Expeditionary Force

Answering Sir A MARKHAM, Mr TENNANT (Under Secretary for War) said There are 43 dentists employed with the Expeditionary Forces in France exclusive of those employed with the Canadian contingent

Uninoculated Officers

In reply to Mr ANDERSON, Mr TENNANT said A commanding officer of any unit would be within his rights and powers in preventing any uninoculated officer from proceeding on active service overseas, because such an officer may, if he contracts enteric fever, be a grave source of danger to his brother officers and the men under his command

Panel Practitioners in England

Sir E CORNWALL asked the representative of the National Insurance Commissioners what was the number of doctors now on the panel in London and in the provinces respectively, as compared with the totals on July 1st, 1914 —Mr C ROBERTS answered, The figures on July 1st, 1914, are not obtainable without a special return from Insurance Committees, but the figures for January, 1914 which would not differ materially from those of the following July were London, 1400, other English areas 14,600 (including doctors on more than one panel) The corresponding figures of doctors who will be on the panel for 1916 are approximately In London 1440, in other English areas 14,400 These figures include a number of medical men on military service whose names remain on the panel whilst some other doctor or doctors are undertaking to carry out their duties

TUESDAY, DEC 21ST

The Drug Tariff

Mr BOOTH asked the representative of the National Insurance Commissioners whether the Commissioners had asked the London Insurance Committee to administer the new drug tariff for 1916, whether the Committee on Thursday declined to receive a report that they should do so whether a special committee had been appointed to examine further the Commissioners' proposal, whether he could see his way to modify the scheme so as to avoid an increase of staff, and was he aware that it was estimated that at least £4000 additional yearly cost would fall upon London to carry out the larger part of the Commissioners' proposals —Mr C ROBERTS said, in reply The duty of pricing prescriptions has been transferred to Insurance Committees by regulations recently framed in accordance with the recommendations of the Departmental Committee on the Drug Tariff, and it is the statutory duty of Committees to make administrative provision for the purpose of calculating the payments due to chemists under the agreements already entered into for 1916. The Commissioners have been in communication with the Committee as to the arrangements necessitated by this duty which they understand are in course of preparation by the Committee Committees have already been informed that special provision will be made for meeting any additional expenditure properly incurred by them on this work out of sums released in consequence of the new tariff arrangements Any such estimate as is suggested of the additional cost involved would appear, however, to be in excess of all reasonable anticipation

WEDNESDAY, DEC 22ND

First Eastern General Hospital

Sir F BANBURY asked the Under Secretary of State for War whether the kitchen arrangements in the First Eastern General Hospital were planned for 520 patients and whether they now had to provide for 1500 patients, whether the commandant of this hospital was in charge of two other institutions, and what salary did he receive —Mr TENNANT replied The facts are substantially as stated in the first part of the question The hospital has expanded and outgrown the original kitchen accommodation The question of improving the kitchen arrangements has been taken in hand, and I hope the defects will soon be remedied In the expansion two other section hospitals have been formed which are in the general charge of the commandant of the hospital and administered under him by officers commanding sections The commandant is a colonel in the Territorial Force, Army Medical Service, and draws the pay of his rank.

Medical Missions to Serbia

Mr MILLS asked the Secretary of State for Foreign Affairs whether any list of the doctors and nurses who had left Serbia had been received by His Majesty's Government, and if so, whether such list would be published —Sir EDWARD GREY wrote in reply No list has been received Our latest information is that Sir Ralph Paget arrived at Brindisi on Dec 18th with 120 members of the medical missions to Serbia

Vaccination Acts in Dublin

Mr NUGENT asked the Chief Secretary to the Lord Lieutenant in Ireland whether he was aware that Dublin soldiers who were fighting in the trenches had recently been prosecuted and convicted in their absence as defaulters under the Vaccination (Ireland) Act, was he aware that if those soldiers had resided in Great Britain they would have been able to avoid the risk of such proceedings by making a declaration of conscientious objection to the vaccination of their children, and whether he will give instructions to boards of guardians in Ireland for the suspension of the issuing of summonses for non vaccination until such opportune time as the law on this subject should in Ireland be made similar to that which obtained in Great Britain and thus conform to the recommendations of the Royal Commission on Vaccination —Mr BIRRELL (in a written answer) replied Legal proceedings have recently been instituted in Dublin against defaulters under the Vaccination Acts The papers did not show whether the persons in default were civilians or whether any of them belonged to the army There are no exemptions from vaccination and it would

most unfair if children were not protected from small pox while their fathers were at the war As regards the latter part of the question, I would refer the honourable Member to a previous reply on the subject

THURSDAY, DEC 23RD

Epsom Asylum

Replying to Mr TYSON WILSON, Sir JOHN SIMON (the Home Secretary) said that owing to the paramount need for economy the Treasury had felt it their duty to object to a further loan for carrying out the contract for the erection of an asylum at Epsom Negotiations with the contractor were still pending He was informed that none of the blocks could be completed under 12 months apart from lighting, heating, and drainage The question of using them as hospitals for wounded soldiers had been considered by the Army Council but the Council did not think it necessary to complete the blocks for this purpose

Tuberculosis Treatment

Sir EDWIN CORNWALL asked the representative of the National Insurance Commissioners to state the amount contributed under the Act in respect of the treatment of tuberculosis cases in this country in the four years ending March, 1915 —Mr C ROBERTS wrote in reply Subject to some slight adjustment the amount available under Section 162 of the National Insurance Act, 1911, in respect of the period July 15th, 1912, to Dec 31st, 1914, for defraying the expenses of sanatorium benefit in the United Kingdom is £2,150,000 Further, a sanatorium benefit grant of £100 000 was voted in the supplementary estimates for 1914–15, £50 000 being paid into the special account for credit to the four National Health Insurance Funds and the balance being revoted in the estimates for 1915–16 I may add that these figures do not include sums of £125,000, £180,000, £480,000, and £385,000 voted in the estimates (original and supplementary) for 1913–14 and in the estimates for 1914–15 and 1915–16 respectively as provision for statutory grants under Section 17 of the National Insurance Act 1911, and for special grants towards the cost of schemes undertaken by local authorities or combinations of local authorities with the approval of the departments administering the grants for the treatment of tuberculosis generally

A Leprous German Prisoner

Mr BUTLER LLOYD asked the Under Secretary for War whether he was aware that a German prisoner of war, in an advanced condition of leprosy, had been kept for many months, in spite of repeated remonstrances from the officer of the guard of the King's Shropshire Light Infantry, within a few paces of the sentry and guard room at Handsforth, near Manchester, and whether he would take immediate steps to have him removed to a more suitable locality —Mr TENNANT answered Special accommodation has been prepared for this prisoner of war at a hospital at Dartford and he is now being removed there

Mr E HARVEY Would it not be possible to make arrangements to send this prisoner back in the next party of exchanged prisoners?—Mr TENNANT I do not think that would be a good thing to do

Medical Men and Service in the Army

Mr PRINGLE asked the Prime Minister whether civilian doctors up to 45 years of age were being asked to join the Royal Army Medical Corps, whether he was aware that doctors already in the service were in many cases performing routine and other duties which could be equally well performed by men who had not a medical qualification, and if so, whether arrangements would be made to relieve doctors in the service of such duties before further depleting the number of doctors available for the civilian population —Mr ASQUITH answered There is urgent need for qualified medical men due to wastage and the necessity for equipping new units My information does not support the allegation contained in the last part of the question

The Needs of the Civil Population

On the motion for the adjournment for the Christmas recess

Mr PRINGLE called attention to the employment of medical men in the service of the army and the further drafts upon the civilian doctors which were being made at the present time The depletion of the supply of civilian doctors was becoming a serious matter for the whole civil population and the country, and obviously a large number of further doctors would be required with the million of men for the raising of whom the House had just granted authority He wanted to know whether the War Office was going to recruit medical men for the new forces on the same scale as they had been recruited for the armies that had been raised, and whether their services were to be used as wastefully and as uneconomically as those of the doctors who were at present serving He would only deal with certain branches of the subject At the present time there were many field ambulances in this country all with a full complement of medical officers, and the great majority of those officers were doing practically no medical work At least their medical work was negligible in quantity The great majority of them had nothing to do but to attend to the feet of recruits That was a wasteful use of the services of skilled medical men These ambulances could be dealt with by a much smaller number of skilled medical men, and if the skilled medical men who were thus being uselessly employed were set free their services would be at the disposal of the civil population, or at least some of them could be withdrawn from their present units and employed for the purposes of the further million men who were to be raised Appeals were now being made in various parts of the country to civilian doctors He knew of one district in London where only ten days ago a meeting of all the medical men was called on behalf of the British Medical Association, and it was there intimated that it was the desire of the War Office that all medical men under 45 years of age should put their services at the disposal of the army If that was done there would be a famine of doctors for the civil population That was a situation which ought not to be allowed to come to pass It was not only in regard to the field ambulances in this country that he had to direct the attention of the Under Secretary for War There was a similar situation in regard to field ambulances abroad It was true that these field ambulances were extremely busy when attacks took place or when our forces had a push against the enemy, but at other times the medical officers attached to these ambulances were largely idle They had no employment With regard to base hospitals the situation was the same There were, in normal times, far too many medical officers for the work which they had to do and when a period of hard pressure came the services of the medical men were needlessly taken up with clerical work and with surgical dressings, which could quite well be done by those who had no medical qualifications The sole work of medical men enlisted in the army should be to devote their energies and attention to the care of the sick and the wounded There were many other details upon which the medical organisation was open to criticism He was told on authority which he considered good that there were large numbers of specialists who were now being employed for ordinary medical work All these things constituted a case for inquiry and for reorganisation. Mr E HARVEY Would it not be possible to make arrangements to send this prisoner back in the next party of exchanged prisoners?—Mr TENNANT I do not think that would be a good thing to do

Medical Men and Service in the Army

Mr PRINGLE asked the Prime Minister whether civilian doctors up to 45 years of age were being asked to join the Royal Army Medical Corps, whether he was aware that doctors already in the service were in many cases performing routine and other duties which could be equally well performed by men who had not a medical qualification, and, if so, whether arrangements would be made to relieve doctors in the service of such duties before further depleting the number of doctors available for the civilian population—Mr ASQUITH answered There is urgent need for qualified medical men due to wastage and the necessity for equipping new units My information does not support the allegation contained in the last part of the question

The Needs of the Civil Population

On the motion for the adjournment for the Christmas recess,

Mr PRINGLE called attention to the employment of medical men in the service of the army and the further drafts upon the civilian doctors which were being made at the present time The depletion of the supply of civilian doctors was becoming a serious matter for the whole civil population and the country, and obviously a large number of further doctors would be required with the million of men, for the raising of whom the House had just granted authority He wanted to know whether the War Office was going to recruit medical men for the new forces on the same scale as they had been recruited for the armies that had been raised, and whether their services were to be used as wastefully and as uneconomically as those of the doctors who were at present serving He would only deal with certain branches of the subject At the present time there were many field ambulances in this country all with a full complement of medical officers, and the great majority of those officers were doing practically no medical work At least their medical work was negligible in quantity The great majority of them had nothing to do but to attend to the feet of recruits That was a wasteful use of the services of skilled medical men These ambulances could be dealt with by a much smaller number of skilled medical men, and if the skilled medical men who were thus being uselessly employed were set free their services would be at the disposal of the civil population, or at least some of them could be withdrawn from their present units and employed for the purposes of the further million men who were to be raised Appeals were now being made in various parts of the country to civilian doctors He knew of one district in London where only ten days ago a meeting of all the medical men was called on behalf of the British Medical Association, and it was there intimated that it was the desire of the War Office that all medical men under 45 years of age should put their services at the disposal of the army If that was done there would be a famine of doctors for the civil population That was a situation which ought not to be allowed to come to pass It was not only in regard to the field ambulances in this country that he had to direct the attention of the Under Secretary for War There was a similar situation in regard to field ambulances abroad It was true that these field ambulances were extremely busy when attacks took place or when our forces had a push against the enemy, but at other times the medical officers attached to these ambulances were largely idle They had no employment With regard to base hospitals the situation was the same There were, in normal times, far too many medical officers for the work which they had to do, and when a period of hard pressure came the services of the medical men were needlessly taken up with clerical work and with surgical dressings, which could quite well be done by those who had no medical qualifications The sole work of medical men enlisted in the army should be to devote their energies and attention to the care of the sick and the wounded There were many other details upon which the medical organisation was open to criticism He was told on authority which he considered good that there were large numbers of specialists who were now being employed for ordinary medical work All these things constituted a case for inquiry and for reorganisation The large number of civilian doctors who had gone into the army did not take kindly to red tape methods The honourable Member also called attention to the fact that since the beginning of the war there had not been a single meeting of the Medical Advisory Committee

Mr TENNANT By design

Mr PRINGLE That is all the worse He did not believe that good results could be attained by consulting men singly

Clerical Work in the Royal Army Medical Corps

Mr DOUGLAS HALL said that he must endorse what the honourable Member had said about the uneconomic use of medical men at the front A great many surgeons out there never did anything but administrative work. There were many medical men there, highly qualified men, who never went near a patient and never went into the operating-room at all They were simply there as clerks to fill up endless forms and to administer the discipline of the orderlies He had been five months at the front and had had to do with a great many hospitals In every hospital there were one or two medical officers who spent nearly all their time in office work The War Office might consider whether it would not be possible to allocate some of these duties to some officer who had not got the high medical skill which officers of the Royal Army Medical Corps possessed He thought that anyone who went out to one of our large bases would be surprised at the number of doctors who at one time were doing no work at all, while other places were suffering for want of doctors He did not know whether that could be avoided, but it seemed to him that there might be some better system for distributing the medical men where they were wanted

The Government Reply

Mr TENNANT (Under Secretary for War) replied In all the actions that have been taken by the medical authorities in the War Office in the administration of the medical services in the army there have been constant and continuous association and conference with the civil medical services of this country The closest touch has been kept with the civil medical profession, and when my honourable friend complains that the Medical Advisory Committee has not met I really must say once again that it seems a little absurd to criticise the War Office for not having had formal meetings of the Committee when the members of that Committee are meeting the authorities and those responsible for the administration of the medical services of the army day by day and almost hour by hour That does seem to me

The Establishment of the Army

The House of Commons has authorised an addition of 1,000,000 men to the land forces of the Crown, bringing the establishment up to 4,000,000

Midwives (Scotland) Act

The Midwives (Scotland) Act received the Royal assent on Thursday, Dec 23rd.

The Christmas Recess

Parliament has risen for a short Christmas recess The House of Commons will resume on Tuesday, Jan 4th During the debate on the adjournment for the holidays, various points relating to the recruitment of the Royal Army Medical Corps and to the details of its administration were raised Mr TENNANT, the Under Secretary for War, replied to the discussion on these matters

HOUSE OF COMMONS

MONDAY, DEC 20TH

German and Austrian Medical Men

Commander BELLAIRS asked the Under Secretary for Foreign Affairs how many German and Austrian doctors and so-called German and Austrian Red Cross employees had been allowed to go through our naval blockade under safe conducts to Europe and how many under instructions from the Foreign Office without safe conduct, and what equivalent was obtained from Germany in the number of British subjects released—Lord ROBERT CECIL replied The number of such persons given safe conducts is 86 and the number of those who were to be allowed to pass without safe conducts is 69 I am not aware of the precise number in each category who may have been arrested on the way owing to suspicion of fraud, but the number is not large With regard to the last part of the question, His Majesty's Government have not so far felt obliged to refuse requests made to them on the ground of the Geneva Convention for the free passage of enemy doctors and Red Cross employees returning to their own country from overseas In most cases doctors and Red Cross officials captured or detained by the Germans have been also released But as in some cases they have not done so, His Majesty's Government is considering the advisability of detaining similar German individuals who would otherwise be returned

Hospital Units in the Balkans

Mr ALDEN asked the Under Secretary for Foreign Affairs whether he was able to make any statement regarding the present position of the various hospital units from England and Scotland that had been compelled to leave Serbia —Lord ROBERT CECIL answered Sir Ralph Paget, who is acting for His Majesty's Government in this matter, has succeeded in collecting the members of the British units who had escaped from Serbia at San Giovanni di Medua, from where it is hoped to transport them to Italy Till transport is provided, which I hope will be very shortly, Sir Ralph Paget may be trusted to do all that is possible for the safety and comfort of the units under his charge

Recruits and Minor Physical Defects

Mr BOYTON asked the Financial Secretary to the War Office whether he was aware that a number of proposed recruits were rejected for minor physical defects, many of which could be successfully dealt with in general hospitals, and whether His Majesty's Government would consider the desirability of paying those who offered to undergo operations or treatment at army rates with dependent allowances whilst they were detained in hospital, provided that they had previously attested —Mr FORSTER replied The number of men rejected for physical defects of a kind which could be cured by surgical operations is inconsiderable, and the risk and disadvantages of the course suggested are so serious that I fear I cannot adopt it

Dentists with the Expeditionary Force

Answering Sir A MARKHAM, Mr TENNANT (Under Secretary for War) said There are 43 dentists employed with the Expeditionary Forces in France exclusive of those employed with the Canadian contingent

Uninoculated Officers

In reply to Mr ANDERSON, Mr TENNANT said A commanding officer of any unit would be within his rights and powers in preventing any uninoculated officer from proceeding on active service overseas, because such an officer may, if he contracts enteric fever, be a grave source of danger to his brother officers and the men under his command

Panel Practitioners in England

Sir E CORNWALL asked the representative of the National Insurance Commissioners what was the number of doctors now on the panel in London and in the provinces, respectively, as compared with the totals on July 1st 1914 —Mr C ROBERTS answered, The figures on July 1st, 1914, are not obtainable without a special return from Insurance Committees, but the figures for January, 1914, which would not differ materially from those of the following July were London, 1400, other English areas 14,600 (including doctors on more than one panel) The corresponding figures of doctors who will be on the panel for 1916 are approximately In London 1440, in other English areas 14,400 These figures include a number of medical men on military service whose names remain on the panel whilst some other doctor or doctors are undertaking to carry out their duties

TUESDAY, DEC 21ST

The Drug Tariff

Mr BOOTH asked the representative of the National Insurance Commissioners whether the Commissioners had asked the London Insurance Committee to administer the new drug tariff for 1916, whether the Committee on Thursday declined to receive a report that they should do so whether a special committee had been appointed to examine further the Commissioners' proposal, whether he could see his way to modify the scheme so as to avoid an increase of staff, and was he aware that it was estimated that at least £4000 additional yearly cost would fall upon London to carry out the larger part of the Commissioners' proposals —Mr C ROBERTS said, in reply The duty of pricing prescriptions has been transferred to Insurance Committees by regulations recently framed in accordance with the recommendations of the Departmental Committee on the Drug Tariff, and it is the statutory duty of Committees to make administrative provision for the purpose of calculating the payments due to chemists under the agreements already entered into for 1916 The Commissioners have been in communication with the Committee as to the arrangements necessitated by this duty which they understand are in course of preparation by the Committee Committees have already been informed that special provision will be made for meeting any additional expenditure properly incurred by them on this work out of sums released in consequence of the new tariff arrangements Any such estimate as is suggested of the additional cost involved would appear, however, to be in excess of all reasonable anticipation

WEDNESDAY, DEC 22ND

First Eastern General Hospital

Sir F BANBURY asked the Under Secretary of State for War whether the kitchen arrangements in the First Eastern General Hospital were planned for 520 patients and whether they now had to provide for 1500 patients, whether the commandant of this hospital was in charge of two other institutions, and what salary did he receive —Mr TENNANT replied The facts are substantially as stated in the first part of the question The hospital has expanded and outgrown the original kitchen accommodation The question of improving the kitchen arrangements has been taken in hand, and I hope the defects will soon be remedied In the expansion two other section hospitals have been formed which are in the general charge of the commandant of the hospital and administered under him by officers commanding sections The commandant is a colonel in the Territorial Force, Army Medical Service, and draws the pay of his rank

Medical Missions to Serbia

Mr MILLS asked the Secretary of State for Foreign Affairs whether any list of the doctors and nurses who had left Serbia had been received by His Majesty's Government and if so, whether such list would be published —Sir EDWARD GREY wrote in reply No list has been received Our latest information is that Sir Ralph Paget arrived at Brindisi on Dec 18th with 120 members of the medical missions to Serbia

Vaccination Acts in Dublin

Mr NUGENT asked the Chief Secretary to the Lord Lieutenant in Ireland whether he was aware that Dublin soldiers who were fighting in the trenches had recently been prosecuted and convicted in their absence as defaulters under the Vaccination (Ireland) Act, was he aware that if those soldiers had resided in Great Britain they would have been able to avoid the risk of such proceedings by making a declaration of conscientious objection to the vaccination of their children, and whether he will give instructions to boards of guardians in Ireland for the suspension of the issuing of summonses for non vaccination until such opportune time as the law on this subject should in Ireland be made similar to that which obtained in Great Britain and thus conform to the recommendations of the Royal Commission on Vaccination —Mr BIRRELL (in a written answer) replied Legal proceedings have recently been instituted in Dublin against defaulters under the Vaccination Acts The papers did not show whether the persons in default were civilians or whether any of them belonged to the army There are no exemptions from vaccination and it would

most unfair if children were not protected from small pox while their fathers were at the war As regards the latter part of the question, I would refer the honourable Member to a previous reply on the subject

THURSDAY, DEC 23RD

Epsom Asylum

Replying to Mr TYSON WILSON, SIR JOHN SIMON (the Home Secretary) said that owing to the paramount need for economy the Treasury had felt it their duty to object to a further loan for carrying out the contract for the erection of an asylum at Epsom Negotiations with the contractor were still pending He was informed that none of the blocks could be completed under 12 months apart from lighting heating, and drainage The question of using them as hospitals for wounded soldiers had been considered by the Army Council but the Council did not think it necessary to complete the blocks for this purpose

Tuberculosis Treatment

Sir EDWIN CORNWALL asked the representative of the National Insurance Commissioners to state the amount contributed under the Act in respect of the treatment of tuberculosis cases in this country in the four years ending March, 1915 —Mr C ROBERTS wrote in reply Subject to some slight adjustment the amount available under Section 162 of the National Insurance Act 1911 in respect of the period July 15th, 1912, to Dec 31st, 1914 for defraying the expenses of sanatorium benefit in the United Kingdom is £2,150 000 Further, a sanatorium benefit grant of £100 000 was voted in the supplementary estimates for 1914–15, £50 000 being paid into the special account for credit to the four National Health Insurance Funds and the balance being revoted in the estimates for 1915-16 I may add that these figures do not include sums of £125 000 £180,000, £450,000, and £385 000 voted in the estimates (original and supplementary) for 1913–14 and in the estimates for 1914–15 and 1915–16 respectively as provision for statutory grants under Section 17 of the National Insurance Act 1911, and for special grants towards the cost of schemes undertaken by local authorities or combinations of local authorities with the approval of the departments administering the grants for the treatment of tuberculosis generally

A Leprous German Prisoner

Mr BUTLER LLOYD asked the Under Secretary for War whether he was aware that a German prisoner of war, in an advanced condition of leprosy, had been kept for many months, in spite of repeated remonstrances from the officer of the guard of the King s Shropshire Light Infantry, within a few paces of the sentry and guard room at Handsforth, near Manchester, and whether he would take immediate steps to have him removed to a more suitable locality —Mr TENNANT answered Special accommodation has been prepared for this prisoner of war at a hospital at Dartford and he is now being removed there

Mr E HARVEY Would it not be possible to make arrangements to send this prisoner back in the next party of exchanged prisoners?—Mr TENNANT I do not think that would be a good thing to do

Medical Men and Service in the Army

Mr PRINGLE asked the Prime Minister whether civilian doctors up to 45 years of age were being asked to join the Royal Army Medical Corps, whether he was aware that doctors already in the service were in many cases performing routine and other duties which could be equally well performed by men who had not a medical qualification and if so whether arrangements would be made to relieve doctors in the service of such duties before further depleting the number of doctors available for the civilian population —Mr ASQUITH answered There is urgent need for qualified medical men due to wastage and the necessity for equipping new units. My information does not support the allegation contained in the last part of the question

The Needs of the Civil Population

On the motion for the adjournment for the Christmas recess

Mr PRINGLE called attention to the employment of medical men in the service of the army and the further drafts upon the civilian doctors which were being made at the present time The depletion of the supply of civilian doctors was becoming a serious matter for the whole civil population and the country and obviously a large number of further doctors would be required with the million of men for the raising of whom the House had just granted authority He wanted to know whether the War Office was going to recruit medical men for the new forces on the same scale as they had been recruited for the armies that had been raised, and whether their services were to be used as wastefully and as uneconomically as those of the doctors who were at present serving He would only deal with certain branches of the subject At the present time there were many field ambulances in this country all with a full complement of medical officers, and the great majority of those officers were doing practically no medical work At least their medical work was negligible in quantity The great majority of them had nothing to do but to attend to the feet of recruits That was a wasteful use of the services of skilled medical men These ambulances could be dealt with by a much smaller number of skilled medical men, and if the skilled medical men who were thus being uselessly employed were set free their services would be at the disposal of the civil population, or at least some of them could be withdrawn from their present units and employed for the purposes of the further million men who were to be raised Appeals were now being made in various parts of the country to civilian doctors He knew of one district in London where only ten days ago a meeting of all the medical men was called on behalf of the British Medical Association, and it was there intimated that it was the desire of the War Office that all medical men under 45 years of age should put their services at the disposal of the army If that was done there would be a famine of doctors for the civil population That was a situation which ought not to be allowed to come to pass It was not only in regard to the field ambulances in this country that he had to direct the attention of the Under Secretary for War There was a similar situation in regard to field ambulances abroad. It was true that these field ambulances were extremely busy when attacks took place or when our forces had a push against the enemy, but at other times the medical officers attached to these ambulances were largely idle They had no employment With regard to base hospitals the situation was the same There were, in normal times, far too many medical officers for the work which they had to do and when a period of hard pressure came the services of the medical men were needlessly taken up with clerical work and with surgical dressings, which could quite well be done by those who had no medical qualifications The sole work of medical men enlisted in the army should be to devote their energies and attention to the care of the sick and the wounded There were many other details upon which the medical organisation was open to criticism He was told on authority which he considered good that there were large numbers of specialists who were now being employed for ordinary medical work All these things constituted a case for inquiry and for reorganisation The large number of civilian doctors who had gone into the army did not take kindly to red tape methods The honourable Member also called attention to the fact that since the beginning of the war there had not been a single meeting of the Medical Advisory Committee

Mr TENNANT By design

Mr PRINGLE That is all the worse He did not believe that good results could be attained by consulting men singly

Clerical Work in the Royal Army Medical Corps

Mr DOUGLAS HALL said that he must endorse what the honourable Member had said about the uneconomic use of medical men at the front A great many surgeons out there never did anything but administrative work. There were many medical men there highly qualified men, who never went near a patient and never went into the operating-room at all They were simply there as clerks to fill up endless forms and to administer the discipline of the orderlies He had been five months at the front and had had to do with a great many hospitals In every hospital there were one or two medical officers who spent nearly all their time in office work The War Office might consider whether it would not be possible to allocate some of these duties to some officer who had not got the high medical skill which officers of the Royal Army Medical Corps possessed He thought that anyone who went out to one of our large bases would be surprised at the number of doctors who at one time were doing no work at all, while other places were suffering for want of doctors He did not know whether that could be avoided but it seemed to him that there might be some better system for distributing the medical men where they were wanted

The Government Reply

Mr TENNANT (Under Secretary for War) replied In all the actions that have been taken by the medical authorities in the War Office in the administration of the medical services in the army there have been constant and continuous association and conference with the civil medical services of this country The closest touch has been kept with the civil medical profession, and when my honourable friend complains that the Medical Advisory Committee has not met I really must say once again that it seems a little absurd to criticise the War Office for not having had formal meetings of the Committee when the members of that Committee are meeting the authorities and those responsible for the administration of the medical services of the army day by day and almost hour by hour That does seem to me

a charge which it does not lie in the mouth of any honourable Member to make

Mr PRINGLE What is the use of having the Committee?

Mr TENNANT I do not follow the observation My honourable friend says that there ought to be fewer medical men in the field ambulances I hope my honourable friend will recognise that it is not only desirable but essential that there should be a sufficiently strong professional medical element with each field ambulance That must be admitted as a necessity If field ambulances should be happily out of work and at rest, not tending the wounded, then naturally enough the doctors and the professional element are also, as it were, at rest It is a little like the soldiers at the front who have so many days in the trenches and so many days in reserve It is not a very unnatural circumstance or an improper fact that doctors now and again do get that amount of rest I have been in communication with the Army Medical Department recently and have discussed these matters with them I suggested, and the suggestion was received very well by my medical advisers, that during periods of lesser operations the actual professional element might be reduced somewhat further than it is at the present time, so as to allow some of the officers to be more fully occupied with medical cases and so relieve the strain of which my honourable friend complains He complained also and the honourable Member for the Isle of Wight (Mr Douglas Hall) joined in this complaint, that there was a good deal of unskilled work, clerical work, and other duties undertaken by highly skilled and trained medical men which might be done by clerks That has often been suggested and I have made it my business to inquire whether really clerks could do the work suggested I am assured that the filling in of forms, which my honourable friend has called unskilled work, could not really be undertaken, shall I say, by stockbrokers' clerks or bank clerks, because it requires real professional knowledge to deal with them

Mr DOUGLAS HALL I did not refer to ordinary clerks I thought it might be done by men drawn from other branches of the service.

Mr TENNANT I am assured by the authorities that is really not so, inasmuch as the forms contain complicated medical details, and to deal with them requires knowledge acquired by training in hospitals and clinical work. But I will return to the charge and see whether to some degree the elimination of the doctor from the form filing work cannot be achieved I want to say this about the alleged deficiency of medical men for the civilian population in this country owing to the army having taken so many doctors My figures are rough, and I do not wish to be bound by them But, roughly speaking, there are 36,000 doctors on the Register in this country, and of these only about 30,000 are in actual practice Of the 30,000 we have taken 10,000, or one third That leaves 20,000 for the civil population I would not say that the whole of these 20,000 are doing no sort of work for the army, because many do part-time work for it in their respective localities But they really are not servants of the State I am informed in France—this is unofficial information—that instead of taking one-third of the doctors in the country for the army, as we have done, the French Government have taken two thirds, or just double, and as soon as they take a man they send him straight away from the place in which he practises and put him into a unit some distance away in order that they may claim the whole of his time

Mr PRINGLE Is it not the case that the French War Office has reorganised its medical service recently?

Mr TENNANT I am afraid that I cannot answer that I daresay they have tried to but I do not think that that necessarily involves my statement being inaccurate I do not know whether my honourable friend suggests that it does

Mr PRINGLE I think that it might modify it

Mr TENNANT I want my honourable friend to realise that we have a Medical War Committee which sits constantly in particular areas to see whether there is or is not any real shortage of doctors for the civil population of a particular area These areas we call for our purposes prescribed areas In these areas no doctor is taken for the army That Committee sits quite constantly I do not know whether there is any other point of detail which my honourable friend raised and with which I have not dealt But generally speaking I should like to say this, that I could not help being a little surprised at my honourable friend's tone in dealing with this subject because I thought it was not only a matter of common knowledge but of universal acceptance that the medical services during this war have been a really remarkable achievement I think that the administration of Sir Alfred Keogh, so far from being the object of attack by my honourable friend or any other honourable gentleman in this House, ought really to form the subject of great congratulation to the War Office I feel that myself I feel that the administration of Sir Alfred Keogh is deserving of the highest praise and I believe that my honourable friend the Member for the Isle of Wight will bear that out

Mr DOUGLAS HALL I beg to repudiate any suggestion that I ever attacked Sir Alfred Keogh

Mr TENNANT I meant the administration I never for a moment suggested that my honourable friend had attacked Sir Alfred Keogh

Mr DOUGLAS HALL I never attacked him I only suggested improvements in the clerical work

Mr TENNANT I only said that I thought the honourable Member in his great knowledge and administrative experience at the front would agree with me that the administration of Sir Alfred Keogh was worthy of admiration I ask the honourable Member to say "Yes" or "No"

Mr DOUGLAS HALL I understood that Sir Arthur Sloggett was in control in France

Mr PRINGLE That is not the impression out there

Mr TENNANT I do not mind that I do not wish to detract at all from Sir Arthur Sloggett I think the combined administration of these two men is a matter for admiration rather than for attack

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to THE LANCET *Office directed to the Sub-Editor not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication*

DUNN J B L R C P Edin M R C S has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Preston (West) District of the county of Lancaster

Notes, Short Comments, and Answers to Correspondents

HEALTH AND SANITATION IN CYPRUS

Unusual interest attaches to the Cyprus Blue book report for 1914–15, recently presented to Parliament, in view of what has happened since the outbreak of war It will be remembered that the island came into the occupation of the British in 1878 by virtue of a treaty made between this country and the Porte, under which Cyprus remained nominally part of the Ottoman Empire. In November, 1914, however, on a state of war being declared between Great Britain and Turkey, the former took steps by proclamation to annex the island, which thus became a British possession In October last the English Government made an offer to cede the island to Greece, conditional on the participation of the latter in the cause of the Entente Allies but the proposal came to nothing for the time being, though it may not improbably be revived The Blue-book report has been prepared by Captain C W Orr, Chief Secretary, and a section of it deals with medical and sanitary matters, of which we give the following summary

The sanitary condition and the general health of the island during the year ending March 31st 1915, were satisfactory One case of small pox occurred in Nicosia in April, 1914 but immediate measures of isolation, quarantine, and vaccination were adopted with the result that the disease did not spread and was limited to this one case. In May, however the disease again occurred in a mountain village, Alona, having developed in a woman who had returned from a pilgrimage to Jerusalem, but owing to vigorous measures of isolation there were only four contact cases 7187 vaccinations were performed during the year 341 cases of enteric fever occurred, 8 of which proved fatal The disease continues mild as a rule but there was a severe and sudden outbreak in the month of July in the town of Larnaca, resulting in about 100 cases There were 13 cases of cerebro-spinal meningitis with 8 deaths, as against 25 cases during the previous year There is also a reduction in diphtheria, 8 cases with 3 deaths being reported, as against 21 cases in the previous year Scarlet fever occurred for the first time for many years, there being 6 cases in Larnaca mild in type

The antimalarial campaign, begun in 1913 after the visit of Sir Ronald Ross, resulted in a reduction of malarial cases So far as the campaign was concerned, however, the year was unfavourable the winter being a mild one favourable for the breeding of mosquitoes, which were found living in wells, &c, during the coldest months of the year Exceptionally heavy rains also fell during November and December 1913, and there were heavy and late spring rains in 1914 Notwithstanding these unfavourable conditions, all districts with the exception of Larnaca, which had an increase of 44 cases showed a reduction of the returns of the previous year, the total decrease amounting to 720 cases Generally speaking the disease takes the benign form, pernicious and malignant cases being rarer The mortality is very low, details for those attending out patient dispensaries are wanting, but the returns for diseases and deaths show that there were only 7 deaths out of a total of 355 cases admitted to the hospitals as in-patients—equal to 1·6 per cent

A more extensive spleen census has been made, and much care and interest has been taken by the medical officers in the examination of children A total of 26 941 were examined during the months of October November and December 1914 at the end of the malarial season, of these, 22,799 were found without enlargement 3125 were returned with slight enlargement, whilst 792 and 225 had medium and great enlargement of the organ respectively. These figures give a spleen rate of 15 3, showing a gradual and steady reduction on the rates of previous years.

Under the supervision of the sanitary engineer extensive drainage and other antimalarial measures were carried out in the Larnaca and Famagusta districts Larvicide substances were extensively used throughout the year, and experiments in these substances were continued It has been found that the addition of a small quantity of the substance hitherto used—a compound of crude carbolic, caustic soda, and resin—to crude oil causes rapid spreading and very much increases its efficiency Two of the chief difficulties encountered in the work of mosquito reduction are due to wells and cesspits, both of which are prolific breeding places Cyprus has, generally speaking, a deficient rainfall, and wells have to be used to supplement the supply for domestic purposes The difficulties of finding in Cyprus, particularly in the large towns, adequate supplies of water suitable for domestic a charge which it *does not lie in the mouth of* any honourable Member to make

Mr PRINGLE What is the use of having the Committee?

Mr TENNANT I *do not follow the observation* My honourable friend says that there ought to be fewer medical *men in the field ambulances* I hope my honourable friend will recognise that it is not only desirable but essential that there should be a sufficiently strong professional medical element with each field ambulance That must be admitted as a necessity If field ambulances should be happily out of work and at rest, not tending the wounded, then naturally enough the doctors and *the professional element* are also, as it were, at rest It is a little like the soldiers at the *front* who have so many days in the trenches and so many days in reserve It is not a very *unnatural circumstance* or an improper fact that doctors now and again do get that amount *of rest I have been in communication with the* Army Medical Department recently and have discussed these matters with them I suggested, and the suggestion was received very well by my medical advisers, that during periods of lesser operations the actual professional element might be reduced somewhat further than it is at the present time, so as to allow some of the officers to be *more fully occupied* with medical cases and so relieve the strain of which my honourable friend complains He complained also and the honourable Member for the Isle of Wight (Mr Douglas Hall) joined in this complaint, that there was a good deal of unskilled work, clerical work, and *other duties undertaken by* highly skilled and trained medical men which might be done by clerks *That has often been suggested* and I have made it my business to inquire whether really clerks could do the work suggested I am assured that the filling in of forms which my honourable friend has called unskilled work, could not really be undertaken, shall I say, by stockbrokers' clerks or bank clerks, because it requires real professional knowledge to deal with them

Mr DOUGLAS HALL I did not refer to ordinary clerks I thought it might be done by men drawn from other branches of the service

Mr TENNANT I am assured by the authorities that is really *not so, inasmuch as the forms contain complicated* medical details, and to deal with them requires knowledge acquired *by training in hospitals and clinical work* But I will return to the charge and see whether to some degree the elimination of the doctor from the form filing work cannot be achieved I want to say this about the alleged deficiency of medical men for the civilian population in this country owing to the army having taken so many doctors My figures are rough, and I do not wish to be bound by them But, roughly speaking, there are 36,000 doctors on the Register in this country, and of these only about 30,000 are in actual practice Of the 30 000 we have taken 10,000 or one third That leaves 20,000 for the civil population I would not say that the whole of these 20,000 are doing no sort of work for the army, because many do part-time work *for it in their respective localities* But they really are not servants of the State I am informed in France—this is unofficial *information—that* instead of taking one-third of the doctors in the country for the army, as we have done, the French Government have *taken two thirds*, or just double, and as soon as they take a man they send him straight away from the place in which he practises and put him into a unit some distance away in order that they may claim the whole of his time

Mr PRINGLE Is it not the case that the French War Office has reorganised its medical service recently?

Mr TENNANT I am afraid that I cannot answer that I daresay they *have tried to* but I do not think that that necessarily involves my statement being inaccurate I do not know whether my honourable friend suggests that it does

Mr PRINGLE I think that it might modify it

Mr TENNANT I *want my* honourable friend to realise that we have a Medical War Committee which sits constantly in particular areas to see whether there is or is not any real shortage of doctors for the civil population of a particular area These areas we *call for our purposes* prescribed areas In these areas no doctor is taken for the army That Committee sits quite constantly *I do not know* whether there is any other point of detail which my honourable friend raised and with which *I have not dealt But* generally speaking I should like to say this that I could not help being a little surprised at my honourable *friend's tone* in dealing with this subject because I thought it was not only a matter of common knowledge but of universal acceptance that the medical services during this war have been a really remarkable achievement I think that the administration of Sir Alfred Keogh, so far from being the object of attack by my honourable friend or any other honourable gentleman in this House, ought really to form the subject of great con*gratulation to the War Office* I feel that myself I feel that the administration of Sir Alfred Keogh is deserving of the highest praise and I believe that my honourable friend the Member for the Isle of Wight will bear that out

Mr DOUGLAS HALL I beg to repudiate any suggestion that I ever attacked Sir Alfred Keogh

Mr TENNANT I meant the administration. I never for a moment suggested that my honourable friend had attacked Sir Alfred Keogh

Mr DOUGLAS HALL I never attacked him I only suggested improvements in the clerical work

Mr TENNANT I only said that I thought the honourable Member in his *great* knowledge and *administrative* experience at the front would agree with me that the administration of Sir Alfred Keogh was worthy of admiration I ask the honourable Member to say "Yes" or "No"

Mr DOUGLAS HALL I understood that Sir Arthur Sloggett was in control in France

Mr PRINGLE That is not the impression out there

Mr TENNANT I do not mind that I do not wish to detract at all from Sir Arthur Sloggett. I think the combined administration of these two men is a matter fo admiration rather than for attack.

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to THE LANCET *Office directed to the Sub-Editor not later than 9 o clock on the Thursday morning of each week such information for gratuitous publication*

DUNN J E L R C P Edin M R C S has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Preston (West) District of the county of Lancaster

HUEY J M M B Ch B Glasg has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Millom District of the county of Cumberland

MACKEITH, JOHN M B Glasg has been appointed Medical Officer to the *Tuberculosis Department at the Central London Throat* Nose and Ear Hospital

WEBBER, W W, L R C P Edin M R C S has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Crewkerne District of the county of Somerset

Vacancies.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures original articles and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor

Letters relating to the publication sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title-page to Vol. II of 1915 were given in THE LANCET of Dec. 25th 1915

VOLUMES AND CASES

VOLUMES for the second half of the year 1915 will be ready shortly Bound in cloth, gilt lettered, price 16*s*, carriage extra.

Cases for binding the half year's numbers are now ready Cloth, gilt lettered, price 2*s*, by post 2*s* 4*d*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand, London, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

ALTERATION OF INLAND SUBSCRIPTION RATES

OWING to the alteration in the Inland Newspaper Postal rate, the postage on each copy of THE LANCET will in future be 1*d*, and sometimes 1½*d*

The revised Inland Subscription rates are —

One Year	£1	3	3
Six Months	0	13	8
Three Months	0	7	0

The rates for the Colonies and Abroad (thin paper edition) will be as usual —

One Year	£1	5	0
Six Months	0	14	0
Three Months	0	7	0

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

NEWSPAPERS FOR NEUTRAL COUNTRIES

THE Secretary of the War Office has issued the following order —

> The public are informed that on and after Saturday, November 6th, newspapers, magazines, books, and other printed publications (other than trade circulars) will not be sent forward to neutral European countries unless posted direct from the office of publishers or newsagents who have obtained permission from the War Office for this purpose Persons desiring to send newspapers, &c, to neutral European countries should, therefore, give their orders for execution to publishers or newsagents who have obtained such permission.

The Publisher of THE LANCET has obtained the required permission of the War Office, and he will forward copies direct from the Office to any neutral country on receipt of instructions

---

The following magazines, journals, &c., have been received — Archives of Internal Medicine, Calcutta Medical Journal, American Journal of Obstetrics Interstate Medical Journal, Revue d'Hygiène St. Thomas's Hospital Gazette Journal of Dermatology American Medicine La Clinica Ostetrica, Journal of Tropical Medicine and Hygiene Review of Neurology and Psychiatry Albany Medical Annals use form an obstacle to introducing a system of reservoirs and filter beds with pipe distribution which might otherwise mitigate the evils arising from the use of wells and cesspits

The Nicosia General Hospital has accommodation for 53 beds 1175 patients were admitted during the year, and there were 41 deaths The number of out-patients was 5832 Twenty cases of consumption were admitted, with 8 deaths, these patients were accommodated in a detached building well removed from the general wards, and it has proved of great service in dealing with cases amongst the poor and destitute of the town of Nicosia The maternity wards treated 27 cases during the year The training of native midwives, who are taken from all parts of the island, has been a marked and very beneficial feature of these wards A large amount of surgical work was carried out in the hospital during the year, the operations performed numbering 409, a large proportion being for abdominal cases The hospital is being equipped with electric light and an X ray apparatus is being set up The district hospitals of Larnaca, Limassol, Paphos, Famagusta, and Kyrenia carried out excellent work during the year A new building is being erected at Famagusta, rendered necessary by the extensive development of the town and port The hospital at Larnaca has been greatly improved, the wards are now tiled throughout and thus rendered much more sanitary than with the old wood flooring, which was difficult to keep clean

The number of inmates at the Leper Farm is now 97 There were 12 admissions during the year and 10 deaths All classes and stages of the disease are met with in the farm, anæsthetic, tubercular, and mixed varieties exist At the lunatic asylum the inmates number 92 During the year 25 cases of insanity were admitted, 9 died, and 8 were discharged cured or relieved Criminal lunatics have now been transferred from the prisons of the island to the asylum All kinds of mental diseases are met with, but dementia and epilepsy are commonest

The number of samples analysed at the Government Laboratory was 1759, an increase of 584 over the previous year There was an increase of 528 in the total of samples of food analysed, and the percentage of adulterated samples showed an advance of from 13 8 to 15 7 due mainly to the adulteration of pepper and curdled milk The percentage of adulterated samples of flour has decreased and the quality of flour improved, although several samples were found unfit for food Of 65 samples of curdled milk examined 42 were found to be adulterated with alum Alum retards digestion, is an astringent a purgative in large doses, and an emetic in repeated doses, taken internally in doses of more than 15 grains it is injurious to health It is only added to curdled milk to make the latter set quickly, and its addition is unnecessary, since these analyses were instituted the makers of curdled milk have practically ceased to add alum Besides the work of analysing samples and making preparations and giving expert evidence in criminal cases, the Government analyst gave during the year a course of 104 lectures and demonstrations in elementary theoretical and practical chemistry and the allied sciences Five of the pupils passed the examination and were awarded the Government certificate

The absolute mean of the thermometer for the year was 65 21° F, as compared with 65 24° in the previous year, this is little less than the mean of the last 15 years The winter was an exceptionally warm one, as the thermometer in the screen in Nicosia never fell below the freezing point, and no snow was observed on the Kyrenia hills The lowest temperature at Nicosia was 35° and the highest 103° The average rainfall for the whole island was 21 91 inches, as against 24 66 during the previous year, this shows an improvement the average for the past ten years having been only 19 79 There can be little doubt that the gradual re afforestation carried on by the Forest Department and otherwise since the occupation, is having a beneficial effect on the rainfall and atmospheric conditions of the island

MIDWIVES' GRIEVANCES

To the Editor of THE LANCET

SIR,—There are two matters affecting midwives about which a good deal of clamour has arisen, and although no mention has been yet made of them in your columns real grievances appear to exist Pressure is being exerted on midwives to notify to the medical officer of health or to maternity centres the names of patients who book with them This cuts at professional confidence and may have the result of militating against the early booking which is so essential for antenatal care It looks as though an attempt is even being made to bluff midwives into thinking that this notification is obligatory The second grievance concerns the inspection of lying in homes which duty the London County Council has recently proposed to delegate to the borough councils, and has actually deputed for the present to their Public Control instead of their Health Department The status of the registered midwife is scarcely likely to be raised by coming along with nuisances and eating houses, under the jurisdiction of the sanitary inspector It is good that the Central Midwives Board has reiterated its request to the London County Council to keep the inspection in its own hands

I am, Sir, yours faithfully,

Dec 27th, 1915 FAIR PLAY

MR BYFIELD'S CALCULUS

To the Editor of THE LANCET

SIR—Dr Thomas Fuller records the following of his friend, Mr Nicholas Byfield, which I think should find a place in medical literature Mr Byfield was rector of Isleworth, in Middlesex, where he preached five times every week and was actively employed in parish work till five weeks before his death "notwithstanding there was a stone in his bladder, which, being taken out, weighed, and measured after his death, was found of these prodigious proportions 1 In weight, thirty three ounces and more 2 In measure about the edge, fifteen inches and a half 3 In measure about the length, thirteen inches and above 4 In measure about the breadth, almost thirteen inches It was of a solid substance to look upon, like a flint" The dimensions, weight, and the description of the stone originally appeared in Dr Gouge's preface to the posthumous writings of Mr Byfield, which were probably published near the end of the fifth decade of the seventeenth century I am, Sir, yours faithfully,

Dublin, Dec 18th, 1915 GEORGE FOY

VOLTAIC VERTIGO

To the Editor of THE LANCET

SIR,—Your Paris correspondent alludes in connexion with shell shock to "voltaic vertigo" as though the meaning of this term is a matter of common knowledge A reference to a recent medical dictionary gives "an inclination of the head toward the shoulder on the side of the positive pole when a galvanic current is applied to the vestibular fibres of the eighth nerve" This definition does not quite fit the context Bárány has used the term galvanic vertigo, but without further defining his meaning Perhaps one of your readers could help I am, Sir yours *faithfully*

Dec 27th, 1915 ACUSTICUS

T D M R C P E—A number of severe cases of pulmonary and even laryngeal tuberculosis show a tendency to rapid improvement when removed from the source of infection and placed under tolerably healthy conditions One such case, when in harmony with his previous experience, may rightly help to convince the administrator of the value of a particular remedy, but this personal kind of conviction cannot be transmitted

J H, M D—We agree that the causation of high pulse tension is often obscure, but not that high tension is insufficiently recognised as a cause of sudden death Our correspondent's view of apoplexy or cardiac failure as a digestive reflex would require more support than his bare assertion

F W P, L R C P—This is hardly a time at which any form of strike can be recommended

ERRATUM—In an annotation entitled "The Treatment of Cerebro-spinal Syphilis by Mercurialised Serum which appeared in THE LANCET of Dec 18th 1915, p 1361 the quantity of albuminate of mercury which can be held in solution by 18 c c of human serum is given as 1 grm and the dose recommended for injection as 1/50 or 1/25 grm Grm is of course, in each case an error for *grain* Dr C M Byrne recommended that the dose should be contained in 30 c c of serum and normal saline solution

COMMUNICATIONS not noticed in our present issue will receive attention in our next

TUESDAY —2.30 P.M Surgical Operations (Mr Carson) Clinics — Medical Out patients (Dr A. G Auld); Surgical Out patients (Mr Howell Evans), Nose Throat, and Ear Out-patients (Mr C H Hayton) Radiography (Dr Metcalfe) 3.30 P M Medical In patients (Dr A. J Whiting)

WEDNESDAY —Clinics —2.30 P.M. Throat Operations (Mr C H Hayton) Children Out-patients (Dr T R Whipham); Eye Out-patients (Mr R. P Brooks) Skin Out-patients (Dr H. W Barber) 5.30 P.M Eye Operations (Mr R. P Brooks)

THURSDAY —2.30 P M Gynæcological Operations (Dr A. E Giles) Clinics —Medical Out-patients (Dr A. J Whiting) Surgical Out-patients (Mr Carson); Radiography (Dr Metcalfe) 3 P.M Medical In patients (Dr R M Leslie)

FRIDAY —2.30 P M. Surgical Operations (Mr Howell Evans) Clinics:—Medical Out-patients (Dr A. G Auld) Surgical Out-patients (Mr E. Gillespie) Eye Out-patients (Mr R P Brooks)

THE THROAT HOSPITAL, Golden square W

MONDAY —5.15 P.M. Special Demonstration of Selected Cases
THURSDAY —5 15 P M, Clinical Lecture

For further particulars of the above Lectures, &c see Advertisement Pages

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title page to Vol II of 1915 were given in THE LANCET of Dec 25th, 1915

VOLUMES AND CASES

VOLUMES for the second half of the year 1915 will be ready shortly Bound in cloth, gilt lettered, price 16*s*, carriage extra.

Cases for binding the half year's numbers are now ready Cloth, gilt lettered, price 2*s*, by post 2*s* 4*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world

ALTERATION OF INLAND SUBSCRIPTION RATES

OWING to the alteration in the Inland Newspaper Postal rate, the postage on each copy of THE LANCET will in future be 1*d*, and sometimes 1½*d*

The revised Inland Subscription rates are —

One Year	£1	3	3
Six Months	0	13	8
Three Months	0	7	0

The rates for the Colonies and Abroad (thin paper edition) will be as usual —

One Year	£1	5	0
Six Months	0	14	0
Three Months	0	7	0

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY *REQUESTED* TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

NEWSPAPERS FOR NEUTRAL COUNTRIES

THE Secretary of the War Office has issued the following order —

> The public are informed that on and after Saturday, November 6th, newspapers, magazines, books, and other printed publications (other than trade circulars) will not be sent forward to neutral European countries unless posted direct from the office of publishers or newsagents who have obtained permission from the War Office for this purpose Persons desiring to send newspapers, &c, to neutral European countries should, therefore, give their orders for execution to publishers or newsagents who have obtained such permission

The Publisher of THE LANCET has obtained the required permission of the War Office, and he will forward copies direct from the Office to any neutral country on receipt of instructions

The following magazines, journals &c. have been received — Archives of Internal Medicine, Calcutta Medical Journal American Journal of Obstetrics Interstate Medical Journal Revue d Hygiène St Thomas's Hospital Gazette Journal of Dermatology American Medicine La Clinica Ostetrica, Journal of Tropical Medicine and Hygiene Review of Neurology and Psychiatry, Albany Medical Annals

Communications, Letters, &c., have been received from—

The FitzPatrick Lectures
ON
MEDICINE, MAGIC, AND RELIGION.

Delivered before the Royal College of Physicians of London

By W H R RIVERS, M D Lond,
F R C P Lond, F R S,
FELLOW OF ST JOHN'S COLLEGE, CAMBRIDGE.

LECTURE I

(*Delivered on Nov 4th 191*)

MR. PRESIDENT AND GENTLEMEN,—Medicine, magic, and religion are abstract terms, each of which connotes a large group of social processes, processes by means of which mankind has come to regulate his behaviour towards the world around him Among ourselves these three groups of process are more or less sharply marked off from one another One has gone altogether into the background of our social life, while the other two form distinct social categories widely different from one another and having few elements in common If we survey mankind widely this distinction and separation do not exist There are many peoples among whom the three sets of social process are so closely inter related that the disentanglement of each from the rest is difficult or impossible, while there are yet other peoples among whom the social processes to which we give the name of Medicine can hardly be said to exist, so closely is man's attitude towards disease identical with that which he adopts towards other classes of natural phenomena

METHODS OF INQUIRY

In any attempt to study a social institution there are three chief lines of approach and methods of inquiry We may examine the institution historically, seeking to learn how it has been built up, how this advance has taken place here and that there, we may study the social conditions under which it has progressed in one place, been stationary in another, and degenerated in a third, and we may attempt to go back to its origin and ascertain the steps by which it has become differentiated from other institutions and has acquired an independent existence

A second method is the psychological We may attempt to study the states of mind, individual and collective, which underlie the acts, again individual and collective, the sum of which make up the institution in question.

The third method, which may be called the sociological method, is the inquiry into the relations of the social processes which we are attempting to study to other social processes in order to determine the interactions between the two

Since the object of the FitzPatrick lectures is the study of the history of medicine, it might seem that the first of these three lines of inquiry should form their subject This would certainly be so if medicine were everywhere the independent and self contained institution which it is among ourselves, but if my opening statement is correct this is very far from being the case A necessary preliminary to any knowledge of its history must be the study of its relations to those other social processes with which it is associated This preliminary task will occupy us in these lectures, which will deal with certain prolegomena to the early history of medicine rather than with the history of medicine itself

It would be quite impossible in the time assigned to these lectures to deal with the subject exhaustively My object will be rather to consider lines of inquiry by which the subject may be studied, and for this purpose I shall limit myself as far as possible to one part of the world, viz, Melanesia and New Guinea, which have been especially the field of my own researches, with occasional references to the allied culture of Australia. The time has gone by in sociology when we tried to understand human institutions by comparing examples taken at random from every part of the world The present trend in the science which deals with these matters is to limit inquiries to a series of related peoples If we reach conclusions by means of such inquiries we can then proceed to see if they will apply in other parts of the world

DEFINITION OF THE SOCIAL PROCESSES

I must begin by defining the three kinds of social process which are to be the subject of our study The distinction between magic and religion is one which has long tried the ingenuity of students of human society Among many peoples, including those with whom these lectures will especially deal, it is far from easy to draw any definite line between the two, and we need a term which will include both A word which is sometimes used in this sense in English is magico religious, and, in default of a better, I shall use it occasionally in these lectures The use of this word will imply a certain attitude towards the world If the matter be looked at from our own point of view this attitude would be one in which phenomena are dealt with by supernatural means I say if regarded from our point of view because, of course, the use of the word supernatural implies the existence of the concept of the natural, and it is just this concept, as we have it, which is lacking among the people with whom I shall deal in these lectures The essence of medicine as we now understand it is that it regards disease as a phenomenon subject to natural laws, to be treated as we treat any other department of nature The distinction between the attitude of the modern practitioner of medicine and the magico religious attitude depends on the difference in the concept of disease in the two cases One chief object of these lectures will be to discover what is the nature of the concept of disease among those who fail to distinguish medicine from magic and religion

While the main topic of these lectures will thus be the nature of the concept of disease among certain peoples of rude culture, and the relation of this concept to those underlying magic and religion, it will be interesting to pay attention to the distinction between these two groups of social process A full study of this distinction would take us too far from our main subject, and I must be content to use a provisional distinction which will be useful for descriptive purposes When I speak of magic, I shall mean a group of processes in which man uses rites which depend for their efficacy on his own power or on powers believed to be inherent in, or the attributes of, certain objects and processes which are used in these rites Religion, on the other hand, will comprise a group of processes the efficacy of which depends on the will of some higher power, some power whose intervention is sought by rites of supplication and propitiation Religion differs from magic in that it involves the belief in some power in the universe greater than that of man himself

Magic and religion are thus differentiated from one another by their attitudes towards the means by which man seeks to influence the universe around him Medicine, on the other hand, is a term for a set of social practices by which man seeks to direct and control a specific group of natural phenomena—viz , those especially affecting man himself, which so influence his behaviour as to unfit him for the normal accomplishment of his physical and social functions, phenomena which lower his vitality and tend towards death. By a process of generalisation society has come to classify these phenomena together and has distinguished them from other groups of natural phenomena under the name of disease As I have already said, one of the chief tasks of these lectures will be to ascertain how far this notion of disease, this category of the morbid, exists among the peoples included in our field of study, and we shall do this mainly by means of an inquiry into the processes by which man reacts to those phenomena we call morbid

Concept of Disease by Various Peoples

One way of approaching the problem will be to inquire how far different groups of mankind have set apart certain members of the community to deal with the morbid When we have evidence of such division and specialisation of social functions, we shall have at the same time definite evidence that those who have reached this specialisation of function have also reached a stage of thought in which they separate morbid from other natural phenomena One point of nomenclature may be considered here In dealing with the subject of medicine from the comparative point of view and among peoples of rude culture, we are met by a difficulty arising out of the wealth of the English language in terms for practitioners of the healing art When in these lectures I am to speak of those members of the community whose special business it is to deal with disease am I to call them doctors, medical men, medicine men, physicians, or what? Medicine men might seem the most appropriate of these in that it is not a term used of our own practitioners, and will thus carry with it no connotation derived from our civilisation It suffers, however, from the disadvantage that it comes to be widely used in anthropological literature for sorcerers and dealers in various forms of magic who may have no dealings with the morbid, and certainly exercise no therapeutical activities I propose, therefore, to use the old English term "leech" When I speak of a leech I shall mean a member of society whose special function it is to deal with the cure of disease He may have other functions, such as the formation of rain, the promotion of vegetation, or even the production of disease itself, but in so far as he is dealing with the cure of disease he will be, in the nomenclature I shall use, a leech

One of the methods then, by which we may seek to ascertain how far different peoples of the world distinguish morbid from other natural phenomena is by inquiring how far they distinguish the leech from the sorcerer or the priest The chief line of inquiry, however, will be an examination of the processes by which man at different stages of culture deals with disease We shall find that even when there is no clear differentiation of the leech from other members of society mankind has theories of the causation of disease, carries out proceedings which correspond with those we call diagnosis and prognosis, and finally has modes of treatment which, even if they have little in common with our own remedies, nevertheless may be regarded as making up a definite system of therapeutics

I have said that one of the chief objects of these lectures will be an attempt to discover the nature of the concept of disease held by different peoples I must first say a word about what we mean when we speak of a people possessing and acting on such a concept I do not mean such a clear concept as is held, say, by the writer of a European text book of medicine, a concept capable of being expressed by the formula we call a definition Such a concept is the result of a very advanced process of generalisation and abstraction, and we all know how difficult it is to frame such a definition, even with the large system of exact knowledge which we possess It is evident that when we speak of the concept of disease held by such a people as the Melanesians we mean no exactly formulated definition, but a more or less vague system of ideas, which, though not distinctly formulated by a people, yet directs their behaviour—their reactions towards those features of the environment which we have classified together under the category of disease

Beliefs as to Causation of Disease

One element of the concept of disease, and perhaps the most important, is that it includes within its scope the factor of causation There are usually clear cut ideas concerning the immediate conditions which lead to the appearance of disease One happy result of this fact is that we are able to approach our subject by way of etiology, and are thus led to deal with the medicine of savage peoples from the same standpoint as that of modern medicine, which rests, or should rest entirely upon the foundation of etiology By starting from etiology we shall find ourselves led on as naturally to diagnosis and treatment, as is the case in our own system of medicine

If we examine the beliefs of mankind in general concerning the causation of disease we find that the causes may be grouped in three chief classes (1) human agency, in which it is believed that disease is directly due to action on the part of some human being, (2) the action of some spiritual or supernatural being or, more exactly, the action of some agent who is not human, but is yet more or less definitely personified, and (3) what we ordinarily call natural causes

Among ourselves there are indications of the presence of all three kinds of belief, and this was certainly so in the not very remote past We now only think of human agency in cases of poison and injury, and then only as the means by which the action of natural causes has been directed The second category still exists in the "hand of God" of our statutes and in the oral rites of our religion, but has ceased to take any part in orthodox medicine, though it still plays some part in the behaviour of the laity towards disease In the professional art of medicine and in the practice of the majority of the laity the attitude towards disease is directed by the belief in its production by natural causes, meaning by this a body of beliefs according to which disease comes into being as the inevitable result of changes in our environment quite independent of human or superhuman agency

If, on the other hand, we examine the culture of any savage or barbarous people we find that their beliefs concerning the causation of disease fall in the main into one or other or both of the first two categories, while in many cases the third category can hardly be said to exist, and even then we cannot assign the beliefs to the category of natural causation. I shall deal with these cases more fully in the second lecture. For the present I shall confine my attention to those cases in which the native ideas concerning causation bring them within the realm of magic or religion. In this first lecture I shall deal with cases which must either be definitely classed with magic or belong more nearly to this category than to that of religion.

It would greatly simplify the treatment of our subject if the line of cleavage between the cases of the causation of disease by human and non-human agency corresponded with the distinction between magic and religion. When writing these lectures I was at one time inclined to throw the distinction between magic and religion on one side and describe the facts with which I shall have to deal under the headings of human and non-human agency. Such a plan, however, would only have avoided a difficulty which it is better to face, for if we treat medicine from the sociological standpoint we must study it in relation to other recognised social processes. Unless we are prepared to throw the categories of magic and religion aside altogether, they cannot be ignored in any discussion of the social relations of medicine.

Disease or Injury Ascribed to Magic

The concept of magic which at present holds good in sociology and ethnology is largely influenced by the art called by this name in our own Middle Ages. The best known form of mediæval magic was one in which non-human, spiritual agents took a most important part. These beings acted as the immediate producers of disease and other effects, the magical character of the proceedings resting on the belief that the non-human agents had come in one way or another under the power of the human magician.

The magic of many peoples of rude culture, including those of the area with which I shall especially deal, differs widely from this in that disease or injury is in many cases ascribed to purely human agency, even when to us the real cause of the condition would seem to be obvious. This mode of causation is not merely brought into play to explain cases of illness which have no obvious antecedent, but also those in which what we should call the natural cause is obvious. Thus, if a man is killed or injured by falling from a tree in the Island of Ambrim in the New Hebrides, the fall is not ascribed to a loose branch or to some failure of coördination of the movements of the climber, but the accident, as we loosely call it, is put to the account of a sorcerer. It is probable that the sequence of ideas in the Melanesian mind is that in a business so familiar as that of climbing trees accidents would not happen unless someone had interfered with the normal course of events. If a sorcerer had not loosened a branch or produced an illusion whereby the victim had seen a branch where there was none, he would not have fallen to the ground.

Similarly, death or injury in battle is not ascribed to the superior skill of the enemy or to a failure of defence, but it is believed that a sorcerer has directed the missile of the assailant or has interfered with the defensive motions of the victim or the integrity of his weapons. A case of snake bite is not ascribed to the act which, according to our ideas, is natural to a venomous animal, but it is believed that the snake has been put in the path of the victim by a sorcerer, or has been endowed with special powers by a sorcerer, or it may even be held that the animal which has bitten the victim is no ordinary snake, but the sorcerer himself in snake-like form.

To those whose main category of the causation of disease is human agency there is a firmly rooted belief in this mode of production, not only where causation would otherwise be mysterious or unknown, but also in those cases where the cause would seem, even to the most uninstructed lay mind in our own community, to lie within the province we call natural. It may be noted, moreover, that such ideas concerning the causation of disease are not empty beliefs devoid of practical consequences, but act as the motives for processes of treatment in case of injury or for acts of revenge if the magical process should lead to the death of the victim. If we were so to define magic as to identify it with the exclusive action of human beings, this part of our subject could soon be treated. The art of diagnosis would consist in the discovery of the human agent and the essential element in the treatment would be the use of measures which would lead the sorcerer to put an end to the actions by which he is effecting his maleficent purpose.

In addition to these cases of purely human agency there are many others in which our records tell us explicitly of conditions closely similar to those of our own Middle Ages in which the immediate cause of the disease is the action of some non-human being who is either under the control of human agency from the beginning or is capable of being brought under such control when it is desired to influence the results produced by its action. In such cases the methods of diagnosis and treatment are often indistinguishable from those employed where the morbid condition is ascribed to direct human agency. Disease or injury believed to be produced by spiritual agency is treated without any element of those processes of supplication and propitiation as would be necessary to bring them within the scope of our definition of religion.

In those cases in which a leech acts through the intermediation of non-human beings our records often leave us in doubt whether the curative actions should be regarded as magical or religious. A decision on this question can only be reached through an exact knowledge of the rites, manual and verbal, by which the leech effects his purpose, and it is only rarely that field workers record these, being too often content to base their opinions on inferences contaminated by ideas derived from their own sphere of knowledge and interest.

My own opinion—it is nothing more than an opinion—is that as our exact knowledge of the leechcraft of different parts of the world increases, we shall find that the religious element in medical rites has been underestimated, or even ignored where it exists. At any moment, however, in the history of a science we must base our arguments upon the recorded facts, and in the account which I shall give my object will be to illustrate the difficulties and uncertainties of the subject rather than lay down any definite conclusions.

The cases I shall consider in this lecture are those in which it is believed that disease is directly due to human agency, and those in which on the available evidence it would seem that the methods of diagnosis and treatment depend on power believed to be inherent in the leech and his rites, or become effective through the intermediation of non-human beings who need no definite rites of propitiation and supplication to persuade them to intervene in the curative process In considering these cases it will be useful to distinguish certain classes according to the nature of the process by which it is believed that disease can be produced, the method of treatment being as a rule such as would follow from the nature of the cause

Three main classes may be distinguished (1) Those in which some morbific object or substance is projected into the body of the victim, (2) those in which something is abstracted from the body, and (3) those in which the sorcerer acts on some part of the body of a person or on some object which has been connected with the body of a person in the belief that thereby he can act on the person as a whole These three classes will now be considered in detail

DISEASE ASCRIBED TO OBJECT OR INFLUENCE PROJECTED INTO VICTIM'S BODY

The class of cases in which the cause of disease is supposed to be some object or substance which has been projected into the body of the victim fall into two groups according as the morbific objects have found their way into the body of the victim by direct human agency or by the action of some non human agent Both kinds are of frequent occurrence in Australia, where material objects such as stones, crystals, fragments of bone, or leaves are believed to be projected into the body, in some cases by sorcerers and in other cases by spiritual beings who thus punish intrusion into their sacred haunts or other offence Disease is also produced in this manner among the Masingi of New Guinea.[1]

In Melanesia this mode of production of disease by the projection of material objects into the body seems to be exceptional Where disease is believed to be due to such projection it is usually held that some invisible influence has been projected into the body, and even where some material substance has been introduced, it is not supposed that the object itself produces the disease, which is ascribed rather to some morbific essence or effluvium, of which the material object is but the carrier and visible sign

A good example of such a mode of production of disease which occurs in more than one part of Melanesia is by means of an instrument called in the Banks Islands *tamatetikwa*, or ghost-shooter A mixture of leaves a dead man's bone, and other ingredients are placed in a slender bamboo which the sorcerer holds in his hands with the thumb over the open end till he sees his enemy, when the removal of the thumb allows the evil influence to reach the victim Dr R H Codrington has recorded[2] some dramatic cases in which this method was employed which very well illustrate the profound belief in its efficacy By means of suggestion the ghost-shooter will kill a powerful and healthy man in a couple of days A less direct procedure customary in the Banks Islands, and there called *talamatai*, is to wrap a parcel consisting of a dead man's bone, or part of an arrow which has killed a man, in leaves and place it on the path over which the person whom it is desired to injure will shortly pass The magical principle will spring out of the bundle and pass into the body of the victim

In cases of illness thus caused by the introduction of morbific objects or essences into the body of the patient the treatment follows directly from the etiology, its aim being to extract the object or essence from the body, and thus remove the cause of the disease For this purpose it is not always or even usually necessary to discover the agent by whom the objects have been introduced In communities which ascribe disease to this cause there are men and women who are believed to have the power of removing objects, usually by sucking some part of the body, after which a stone, crystal, or other object is shown to the patient as having been removed by the process Since in many such cases the disease has been produced by a suggestion set in action by the knowledge of some cause of offence to one believed to have the power of producing disease in this way the sight of the object thus said to have been removed effects a rapid cure in removing the suggestion In some cases, and especially in those in which the projected substance is of an immaterial kind, it may be necessary to discover the agent who alone can remove what has been implanted in the body, and in this case some method of divination is usually employed to discover by whom the disease has been produced

DISEASE ATTRIBUTED TO ABSTRACTION OF PART OF BODY OR SOUL

The second mode of production of disease is that in which it is believed that something is abstracted from the body Examples of this occur in Australia, where the abstraction of the kidney fat, or, perhaps more correctly, of the fat of the omentum, forms one of the most widely held beliefs In New Guinea and Melanesia this belief does not, so far as we know, exist, but in many parts of these regions the people believe in the causation of disease by the abstraction of the soul or of some part of it The Melanesian examples of this process are all, so far as we know, due to spiritual agency.

Thus, in the Banks Islands the *atai* or soul may be taken from a man by one of the spirits called *vui* The treatment consists in the recovery of the soul by one called *gismana* whose *atai* leaves his body in sleep and seeks out the soul of the patient[3]

Another example of which we have a full record[4] comes from the Gazelle Peninsula of New Britain and Duke of York Island, where it is believed that disease is produced by one of a group of beings called *kaia* which have the body or tail of a snake and the head of a man The *kaia* usually acts in this way on one who has intruded on its haunts or taken fruit without proper authorisation from trees in the district it inhabits

If anyone falls ill in these places the people resort to a process of divination to determine whether the disease is due to the action of a *kaia* or has arisen in some other way The diviner places under his arm pit a piece of shell money enclosed in a lime strewn banana leaf and falls into a sleep in which he learns not only how the disease has been produced, but, if it is due to a *kaia*, he is able to tell the nature of the fault which has incurred the anger of the half snake half human being The diviner who also acts as a leech then proceeds to carry out his treatment

In the Duke of York Island, lying between the northern end of New Britain and the southern end of New Ireland, this treatment is as follows The leech sprinkles lime on a dracæna leaf, enfolds it in a leaf of another kind and places the packet so formed on a fire until it is almost carbonised The patient then stands with raised arms and the leech passes the hot packet over his body with movements resembling the curves of the body of a snake while the patient stamps on the ground so as to shake off the influence of the *kaia* Then the leech opens the packet and takes therefrom a pinch of lime over which he incants the following formula —

"Lime of exorcism I banish the octopus, I banish the *teo* snake, I banish the spirit of the *Ingiet*[5], I banish the crab, I banish the water snake, I banish the *baliro* snake, I banish the python, I banish the *kaia* dog[6]

[3] W H R Rivers : History of Melanesian Society Cambridge 1914 vol I p 165

[4] J Meier : Anthropos vol III (1908) p 1006

[5] A secret society

[6] A special kind of dog unlike the existing dog of New Britain which forms one of the companions or familiars of the *kaia*. The other animals mentioned in the formula are also familiars of the *kaia*

Lime of exorcism I banish the slimy fluid, I banish the *kete* creeping plant, I banish To Pilana, I banish To Wuwu Tawur, I banish Tumbal. One has sunk them right down deep in the sea. Vapour shall arise to hold them afar, clouds shall arise to hold them afar, night shall reign to hold them afar, darkness shall reign to hold them afar, they shall betake themselves to the depths of the sea"

This is a literal translation of the original, Father Meier gives the following as the expression of its full meaning —

> This is lime for exorcism with which I drive away the octopus, the different kinds of snake, the spirit of the *Ingiet* and the *kaia* dog This is the lime with which I drive away the slime of the *kaia* pool, the creeping plant called *kete* and the *kaia* called To Pilana To Wuwu Tawur, and Tumbal I have sunk them and they are now below in the deepest depths of the sea. Thick vapour, impenetrable cloud dark night and black darkness shall surround them and block their way for ever to the upper world so that they shall remain for ever in the infinite abyss of the sea."

When the formula is finished the leech blows the lime over the patient and more lime is smeared on his body, especially in the epigastric region, on the arms near the shoulders, and on the ears and great toes The packet is then thrown away and the upper part of a coconut three-quarters ripe is husked with the teeth and a hole bored in the shell round which red ochre is smeared The leech then rubs in his hands a bloom of a species of mint, puts the fragments in the nut, and utters the following formula over the nut to act upon its milk.

> The coconut of exorcism I banish the slime of the *kaia*, I banish the slime of the crab, I banish every pool with yellow slime, away with every swarm of *teo*-snakes, away with the spittle of the *teo*-snake, away with To Wuwu-Tawur, away with all the sap of the *kete* creeper; away with every *alai pi kai* creeper, away with all red brown water.[7]
>
> I banish every water of the *kaia*, away with every octopus, away with all the blood of the tree-snake.
>
> I banish every puffed up belly, I banish every dried up shrub and grass, I will fetch his soul again from the hollow[8] of the *kaia*"

The leech then bespatters the patient with saliva, gives him the coconut to drink, takes his fee and goes

This production of disease by the *kaia* comes in several respects very near the domain of religion, but I have included an account of the proceedings connected with it in this lecture because the treatment bears no evidence whatever of any appeal to, or propitiation of, higher powers The attitude towards the *kaia* itself is evidently that of the exorcist acting on a being who is believed to be capable of control by the leech through his knowledge of the proper rites, manual and verbal It is, of course, possible that behind the whole proceedings there may be the idea of appeal to some higher power of which the formulas provide no evidence but we can only act on the evidence before us, and this shows no trace of any such idea. We have here an example of social activity which we must provisionally label as magic, but of a magic which differs fundamentally from that of the Australian or inhabitant of Torres Straits, a magic which approaches in its general character, as well as in many of its details, that of our own Middle Ages It is not a process by which one person counteracts the injurious influence of another person, but one by which a human being, through the knowledge of the appropriate rites, is able to act upon a non human being in such a way as to counteract his influence

MAGICAL ACTION ON SEPARATED PART OF VICTIM S BODY OR TOUCHED OBJECT

The third kind of process which I have included under the heading of magic is that in which disease is believed to be produced by acting upon some separated part of the body of the victim or on some object which has been in contact with him This kind of magic, usually known as sympathetic magic, has been so frequently considered[9] that it is hardly necessary to consider cases in detail I propose to confine my attention to one example, which may help us to understand the exact nature of the process more clearly than has hitherto been possible This example has only recently been recorded by Keysser,[10] a missionary among the Kai, an inland people of the north eastern part of New Guinea. This procedure is of especial interest in that it shows the presence among this people of ideas concerning sympathetic magic which brings it into close relation with our second category in which disease is produced by the abstraction of something from the body According to Keysser, the Kai believe in a soul substance which permeates not only every part of the body, but also extends its presence to anything which has been in contact with the body When a sorcerer secures part of the body of his proposed victim or an object which has been in contact with his body, he is believed to be really securing part of the soul of the person, and it is by the action of his magical processes upon this isolated portion of the soul that the rites of the sorcerer produce their effect

> A sorcerer who thus secures part of the soul substance of one whom he wishes to injure repairs to a lonely hut situated in a spot reputed to be the haunt of a ghost or other spiritual being, so that it is avoided by all except those who have undergone special initiation into this mode of magic or have in some other way acquired knowledge which enables them to visit the spot with impunity Often several sorcerers act in concert, each performing the rites I am about to describe, at first independently and later in concert
>
> The fragment of the body of the victim, or of something which he has touched, by means of which the sorcerer acts, is called *ga* It may be hair a drop of sweat, excrement, remains of food or even a piece of wood which the victim has touched. The *gâ* must have been freshly removed from, or been in contact with, the body of the victim, so that the sorcerer can be confident that it still contains the soul-substance of his victim. In order to ensure its retention the *gâ* is put at once in a piece of bamboo which is hidden and kept warm by being placed in the arm pit of the sorcerer The *ga* must not be taken near fire or smoke nor must it be brought into contact with water or with any sharply pointed object for all these conditions tend to expel the soul substance from its resting place
>
> As soon as possible the sorcerer wraps the *gâ* in a leaf of which caterpillars are fond with the idea that as the leaf is eaten by caterpillars so will the body of the victim be eaten by worms The *gâ* wrapped in the leaf, is put in a small bamboo, which must have been taken from a place inhabited by ghosts or spirits Fragments of the bark of certain trees are added to the packet, some are added in order to make it heavy for it is by means of the weight of the packet that one judges whether the soul substance is present or has disappeared Another tree the bark of which is added has a very thick stem and is used in the hope that the body of the victim will swell, while the bark of other trees is added on account of their evil smell The bamboo and bark are wrapped in another leaf and bound up with a creeper which withers very quickly pointing thus to the rapid wasting and death of the victim The packet so made is closely bound till it is just of a size to go into a larger piece of bamboo, which must also come from the abode of a ghost or spirit This is put in yet another bamboo which is sealed with the inspissated sap of a tree and covered with shells As the packet is thus wrapped and sealed the sorcerer calls to the white cockatoo ' Cockatoo Cockatoo, come and tear open the body of X, bite his entrails to pieces so that he dies" The packet is then bound to a rod and over it are sung words

---

[7] Water containing reddish algæ.

[8] The *kaia* are said to dwell in hollows in the hills

[9] See especially J G Frazer The Magic Art London, 1911 For examples from Melanesia, cf. Rivers, op. cit. i., 156.

[10] In Deutsch Neu-Guinea" by R. Neuhauss, Berlin 1911 vol. III, p 135

by means of which the spirits are summoned from the hollow where they dwell to take the soul of the victim to the home of the dead The packet is wrapped in a prickly creeper so that the body of the victim shall be tormented with painful stings and then in a leaf with fine hairs which tickle and irritate the skin, and the whole is wrapped in a withered leaf of the bread fruit tree, with the idea that as the leaf falls to the ground so shall the body of the victim wither and fall into the grave

During all these proceedings the sorcerer murmurs "Oha and WaLang, ye two giant lizards, lay yourselves on his soul and press upon it so that all joyful springing and all pleasure shall cease Stop his ears so that he no more hears and his thoughts become confused" As these words are uttered the sorcerer beats with his open hand on the packet in order that painful blows may affect the body of the victim The packet is then bound once more with a creeper, while the following formula is uttered "Fall and rot like the gherkins Let the victim disappear in pains May his limbs writhe in pain May his whole body writhe in pain May his entrails become contracted in pain May his generative organs be distorted in pain" These proceedings are not carried out once merely but are repeated again and again, it may be for many months

Every other day the sorcerer enters the lonely hut where he keeps the imprisoned soul and treats it in this way, putting the packet on each occasion upon the ashes of the fire, and this goes on until the victim begins to sicken when the proceedings enter upon a new phase The packet is heated at the fire after being covered with fine prickles, and the bark of a tree covered with tubercles is added so that the body of the victim may be covered with similar lumps The packet is bespattered with the chewed root of a hot peppery plant so that the victim shall have fever The fire at which the packet is heated must be made only of certain woods and of a creeper, the section of which darkens when it is cut, with the idea that the skin of the victim shall darken and his blood become black Every day, if possible, the packet is laid on the fire with the words —

> "Eagle and Hawk Ye both, here is your prey Seize it with sharp claws
> Rend his body and tear it to pieces Then may corruption and worms maggots and beetles utterly destroy his body"

At every repetition of this spell the packet is turned round by an assistant while the sorcerer himself mimics the agony of his victim He cries, shouts, and groans as if in pain He complains to his friends who visit him and prays for help and sympathy, and his assistant comforts him in the way of one who visits a friend in so grievous a situation Finally, the sorcerer groans like a dying man, imitates the death rattle draws his last breath, and pretends to be dead Before leaving the packet for similar treatment on another day he puts it between pieces of wood weighed down with a stone and covers the whole with ashes

In order to reassure himself from time to time that the soul is still in the packet the sorcerer goes to the hut in the darkness and listens If he hears a rustling in the roof of the hut or any other sound he is satisfied that the soul is still there, and that his labours still await their reward To assist his purpose however, he must submit to many hardships and restrictions He must not bathe nor let rain touch his skin He may only drink the water of puddles which have been heated in the sun, for the cool water of a stream would allay the burning fever of his victim Even pure water of any kind may be regarded as unsafe, and the sorcerer may drink only water which has been used for cooking He must not eat boiled vegetables, but must roast his *taro* at a fire During the whole proceedings he must abstain from sexual intercourse, nor should he take food from men who have not so abstained

In the hut where the packet is kept there must be deathly silence No one must speak aloud nor cough loudly All conversation must be conducted in whispers No wood may be broken and such noise as that produced by treading on twigs must be avoided The hut itself consists of two chambers in the smaller of which the packet is kept, and no light is allowed to enter this chamber so that the imprisoned soul may receive no ray of hope for its escape

The whole proceedings reach their climax at a feast which has brought together the people of many parts The sorcerer and his companions leave the rest and assemble in the lonely hut All those who have been carrying out these rites bring their bundles with them These are weighed on the open hand, so as to judge whether the soul is still present, and those found to be too light are set aside The rest are put in an old pot covered with shards strewn with ashes, and surrounded with a ring of fire Then the sorcerers imitate the sickness of the victim, after which the packets are taken from the spot and laid on an open fire so that the outer coverings are consumed with the idea of bringing the disease of the victim to a crisis The sorcerers writhe as if in mortal pain, sigh, groan, and utter loud complaints Their friends visit them, pity them, and express opinions about the people by whom they may have been bewitched While some of the sorcerers are thus simulating mortal sickness, others take the packets from the fire and wring them between pieces of cloth with the idea that the victim shall be smitten with mortal agony, his throat and heart pressed together, his breath driven out, and he himself driven to death by terror and despair The pieces of cloth are cut and each packet falls to the ground while some mimic the death of the victim and others utter his death wail At the same time a tree in the neighbourhood is felled to which the name of the victim is given

Finally, the packet is thrown in the fire so that the coverings are completely burnt and the bamboo vessels within it are wrapped in bark and beaten violently with a stone while the death scene is again portrayed While some lie as if dead upon the ground, others talk about them and their affairs and put on women's head dresses and wail as if they were women They utter the reproaches of one village against another and threaten fearful revenge The wordy war leads to blows, and with cudgels and sticks to represent weapons the sorcerers fight in mockery of the combat which will follow the death of the victim

Treatment Magical or Religious Nature of Rites

The treatment of the morbid conditions produced by these magical proceedings is inspired by beliefs of the same order, consisting of measures to counteract the rites of the sorcerer The method, frequently found elsewhere, in which the sorcerer himself is induced by payments or other means to remove his spell, in this case to release the imprisoned soul substance, is not mentioned by Keysser, but the release of the soul is brought about by other means A friend of the victim may secretly free the soul from its prison, or the liberation may be effected in a symbolic manner A magical receptacle in which some soul substance has been put is rubbed against the breast, back, and legs of the patient to portray the return of his own soul substance to his body, and the receptacle is then torn asunder to show that the soul is free The action is repeated three times, on each occasion with a different formula, and by the power of these actions the soul substance which has not been sufficiently closely bound can again be made free The principle underlying another method is that of the extinction of fire by water, some of the soul substance of the patient being placed in the cool water of a mountain stream In still another method some of the soul substance of the patient is enclosed in leaves and hidden within a hollow stone, which is then thrown into a deep pool The therapeutical measures thus employed by the Kai in order to cure disease produced by magic thus reveal the same dependence of treatment on etiology which we have found among other peoples and in proceedings of other kinds

These elaborate rites of the Kai would be regarded by all ethnologists as an example of magic but they have several features which bring them very near to religion The formulas are not decisive in this respect, though more than one seems to have in it a note of appeal to higher powers Still more significant of the religious attitude is the ordinance that certain of the objects used in the rites must have come from the abode of ghosts or spirits The methods of treatment, on the other hand, seem to be purely magical, and taking the rites as a whole they must certainly be regarded as magical rather than religious

CONCRETE NATURE OF BELIEFS UNDERLYING THE RITES

The rites of the Kai provide characteristic examples of the two kinds of sympathetic magic known respectively as imitative or homœopathic and contagious magic The principle which has hitherto been held to underlie these forms of magic is of a more or less mysterious kind

Thus Sir James Frazer[11] refers the belief in the connexion between a person and a separated part of his body to a relation "which we may conceive as a kind of invisible ether, not unlike that postulated by modern science for a precisely similar purpose—namely, to explain how things can physically affect one another through a space which appears to be empty '

Sir James Frazer does not, of course, intend this explanation of contagious magic to be anything more than a figurative expression in the language of modern science of the modes of thought which determine the actions of savage man Into whatever equivalents however, we translate his language the ideas thus held to form the basis of contagious magic will have an abstract, if not mystical, character which I believe to be opposed to the concrete nature of the mental processes of peoples of rude culture Often the savage performs rites of the most complex kind merely because this course of action has been prescribed for him by the immemorial traditions of his community but where direct motives for his actions can be discovered they have a concrete character very different from that suggested by the metaphor of Sir James Frazer

The special interest of the blend of medicine and magic practised by the Kai lies in the concrete and definite character of the beliefs which underlie these elaborate rites The savage has few concepts more definite than that of the soul and of its continued existence after death We have only to qualify this concept by the addition of the belief that the soul is divisible to give us the principle which underlies the magic of the Kai, a principle as definite as any of those which underlie the religious conduct of civilised man The contagious magic of the Kai rests, not on any mystical belief in action at a distance but on the belief that the sorcerer has in his possession part of the soul of another person, part of the vital essence of the person he wishes to destroy The conduct of the sorcerer might be held to imply a belief that action upon the part is equivalent to action upon the whole, but it is probable that there is rather confusion between part and whole, or more correctly in the case of the Kai between soul and soul substance That this is so is suggested by the confusion between soul and soul substance which occurs in several parts of the account given by Keysser

We only know of the concept of a divisible soul substance in New Guinea and the Malay Archipelago, and we must await further evidence to show how widely diffused it is throughout the world All that we can say now is that this concept affords an explanation of much in the ways of savage man which is at present mysterious and unintelligible

There is probably as little justification for ascribing the other main variety of sympathetic magic to any vague mysterious principle The rites of the Kai are full of acts which show a belief in the efficacy of imitation, many of their features depending on the idea that the imitation of an event will bring that event to pass This principle, often summed up in the phrase, "like produces like," is one in which there is nothing vague or indefinite It may only seem so to the more scientific of our number because we have ceased to believe in it as a law of natural causation, though, as we all know, a variant of it forms the basis of a system of medicine which still flourishes among us Such positive knowledge as we possess concerning the psychological processes underlying the blend of medicine and magic leads us into no mystical dawn of the human mind, but introduces us to concepts and beliefs of the same order as those which direct our own social activities

---

CONTRIBUTIONS TO THE STUDY OF SHELL SHOCK

BEING AN ACCOUNT OF CERTAIN CASES TREATED BY HYPNOSIS

BY CHARLES S MYERS, M D, Sc D, F R S,
MAJOR, R.A.M C. (T C)

II.[1]

IN this communication I propose to describe a selected few of various cases of "shell shock" which I have had the opportunity of treating in the field by means of hypnosis

Total Amnesia

CASE 4 (Case number 390) —Private ——, admitted into a field ambulance and seen by me there three days later, having been found wandering in a neighbouring village, clad only in his shirt and socks He was unable to give his name, regiment or number He thought his age was between 20 and 30 I tried him with various christian names but he replied that none of them seemed familiar to him He could remember two men finding him as he was strolling on the outskirts of a village and could describe everything that had occurred to him since then There was no means of identifying him and his past was a complete blank, he could recall nothing, for instance, of the events of his childhood.

He appeared considerably depressed at his condition, he said that he wished he could recover his memory and that it would be a worry to his people " if he had any belonging to him. He did not complain of any aches or pains, only of numbness over the occiput. His legs were tremulous as he lay on his stretcher his hands were tremulous when held out, and his tongue was faintly tremulous on protrusion His left arm and leg and the left side of his face (not scalp), chest, and abdomen were hypalgesic, his voluntary movements were normal His reflexes, superficial and deep, were normal, save that the knee jerks were exaggerated, and a pseudo-clonus was obtainable at the left knee and at the right ankle His pupils reacted very actively to light, no limitation of visual fields eye movements normal.

He had slept fairly well since his admission to the field ambulance but complained of a nightmare on the night before my visit, when he dreamed that he was in the trenches throwing bombs and that the Germans threw one at him which hit him in the nape of the neck, waking him up "in a cold sweat."

Under hypnosis into which he easily passed, he first repeated to me his dream. Then his thoughts turned to his mother living in a small house in the country, "near a big town ' "where they make anchors and chains " He recalled working with his father as a labourer on hayricks All this information had to be dragged from him piecemeal with considerable difficulty He next recalled the names of the village and of the manufacturing town near by Then he gave me his own name, regiment, and number, but always with uncertainty, qualified, for example, by the words "I think." Finally, he was persuaded to describe what happened after the bomb throwing (for his dream turned out to be an actual event), "I must have gone off my head and run away I must have taken off my clothes in a field I spent the first night under a hedge I spent the next two nights in a wood I ate nothing The next night I was walking along a road on the outskirts of a village, and I was taken to a house by two men " These data, like the preceding, were only extracted with great difficulty and after much persuasion.

---

[11] Op cit vol. I p 54

[1] The first of these communications appeared in THE LANCET of Feb 13th 1915

When he awoke from hypnosis the suggestion which I gave him before waking that he would remember all that he had told me proved only imperfectly effective He could not remember his name, regiment, number, nor the names of his native village and the neighbouring town But in reply to further questions he had a vague recollection of having been dreaming of his mother and of his wanderings, and he could be induced to recall them as well as his former occupation, the town where they make anchors and chains, &c.

When he was rehypnotised without delay, his memory became much clearer and ampler than before, and he was far more certain of his past history He recalled, for example, the standard (7th) at which he left school (at 14) and a punishment he had received since enlistment for "cheeking" a sergeant Then he told me that he had been in France for eight months and had enlisted nine months previously A much more powerful suggestion was brusquely given, followed by a complete recovery of memory on waking from this second period of hypnosis His entire expression changed, his pupils became larger, and his despondency disappeared At the same time the previous occipital numbness and left-sided hypalgesia vanished

Transferred to a base hospital, and thence for three weeks to a hospital in England, he has made an uninterrupted recovery and has now rejoined his unit

Rhythmic Spasmodic Movements

CASE 5 (Case number 362) —Private ——, aged 23, seen by me at a casualty clearing station the day after admission Three days ago, he said the Germans sent over "whizz-bangs and coal boxes" in reply to our shelling, and he had been told that he "got pitched up in the air" But the last thing he remembered of the occasion was being on guard the next was digging himself out of the fallen sand bags He remembered running then to the shell trench, but he "found this too hot" and returned to the firing trench going to his dug out, when he noticed that his eye sight was defective He lay in the dug out, flinching each time a shell came, and "trying to get into the smallest possible corner " At night he came out to endeavour to "do guard," but someone noticed that he was making involuntary spasmodic movements which had begun a short while previously He was ordered to return to the dug out, was helped to the regimental aid post by a man on each side of him, and was sent to hospital He had enlisted for the war and had been in France eight months He had also "got shook up a bit" four months ago, when five or six bombs threw dirt in his face. His hands and his handwriting then became shaky, but he did not "report sick."

His appearance was that of a strong, robust, and honest man He seemed depressed and begged me to make him well His most noticeable movements were in his legs but occasionally he shrugged his shoulders On admission, I am told, the latter movements were much more marked and he kept diving beneath the bedclothes, bringing up his knees to meet his chin To-day the leg movements were due solely to strong, periodic, simultaneous contractions of the two sartorius muscles the rate of contraction of which varied from 60 to 70 per minute increasing to 90 during the excitement of examination These involuntary movements were observed by the sister to continue during apparent sleep Pulling down the patella was found to inhibit one or two contractions of the corresponding sartorius His knees remained extended when the thighs were passively raised from the bed He complained of severe headache ' as if I had had a hammer dropped on my head ' His legs were very tremulous, especially when he lifted them, his hands and tongue were only faintly tremulous His right leg and arm and the right side of the face and chest (not the abdomen) presented certain disturbances of sensibility which can be better described in a later communication devoted to th subject His voluntary movements were normal Only t patellar and plantar reflexes were examined Of these t former were much exaggerated, while the latter could not elicited, probably owing to the rigidity of the feet H pupils were of moderate size and reacted normally to ligh visual fields and eye movements appeared normal

Under hypnosis he was able to recall all the events duri the period of his previous amnesia. He remembered t direction from which the shell came, how he was lifted u how he fell on his back, &c As he passed into a deep state of hypnosis the contractions of the sartorius muscl became very much diminished, but did not absolute disappear Before rousing him from hypnosis, I suggeste that now and on waking he would lose his headache and h involuntary movements, and that he would recover his spiri and his memory The movements at once ceased and h awoke able to stand, absolutely free from his headache a spasmodic movements, with recovery of memory, and other observers spontaneously remarked "looking anoth man " The previous unilateral disturbances of sensibilit were found to have disappeared

He was transferred to a base hospital

Mutism

CASE 6 (Case number 19) —Private ——, aged 32, seen b me the day after admission to a base hospital complete mute, but able to read and write He wrote ' I wa buried alive on —— and again on —— (5 months an 4½ months respectively before admission), and then I ha the misfortune to have two shells burst over me on — (four days before admission) There was shelling for abou 20 minutes and then two bursted over my head I did no remember any more until you came to see me but I am sti liveing in hopes to regain my speech back." In referenc to his first burial he also wrote that he afterwar wandered with Lance Corporal —— for two days, but tha his memory for these two days was completely gone, h comrade and he finally came across men of the Frenc artillery, who enabled them to rejoin their regiment H could not recall how he got his food during those two day He said that this time, although he found a piece of she in his tunic he was unhurt, but that on the first occasio he fell and hurt his back, and suffered for some time fro pains in the back and head and from insomnia, which ha recurred now

His understanding seemed slow and his look wa vacant. Occasionally he made jerky movements of th arms and a noise like a snore came from his naso-pharynx His voluntary movements were restricted, weak, slowl executed, jerky, and incoördinated, but they were no tremulous He could not raise his arms above his head nor could he keep them raised in front of him Even wit his eyes open he failed to touch his nose with his inde finger tip and he stood very unsteadily The sense o position appeared to be unimpaired (cutaneous sensibility not examined) The only vowel he could imitate was A (continental pronunciation), the only consonants S and P His knee jerks were exaggerated, the plantar reflexes were flexor, the abdominal reflexes could not be obtained His pupils were widely dilated but reacted well to light His eyes moved normally His visual fields were somewhat restricted on the temporal side He could not hear a faintly ticking watch, even when in contact with either ear but he heard better by air than by bone conduction His bowels had not been opened since the shock—i.e , for five days He passed urine voluntarily now, but during the journey to the base he was catheterised in the train On my visit the third day after admission he seemed much brighter, and his movements had improved in extent speed and coördination He began to imitate monosyllables, and he explained in writing that he ' cannot think how to speak,' feeling "just like an infant "

By the seventh day all signs of stupor and ataxia had disappeared With great difficulty he managed slowly to repeat after me the names of the county borne by his regiment and of the village in which he lived Next day he could give me these names in response to my questions and could give me the christian names of his wife and child He sweated profusely during these efforts He never spoke of his own accord

Sixteen days after admission his speech was improving but he showed me a report he had written out for me of his condition, and in so doing burst into tears Apparently to-day he had overheard a sister expressing the opinion that he was a malingerer

Under hypnosis he spoke distinctly more fluently, although still with feeble voice power, but on being questioned about trench life he became extremely emotional and suddenly awoke, wiping the sweat from his chest

On the following day, under hypnosis, his speech was at first slow and hesitating, as if he was disinclined to speak Finally after repeated suggestions and encouragement, he was induced to recall the forgotten events on the second occasion of being buried He named the man who pulled him out of the trenches and described the hospital to which he went and his train journey to this base He responded readily to post-hypnotic suggestions that on waking he would remember all that he had told me, would be able to speak louder and more fluently, and would perform certain somewhat eccentric actions

Three days later (three weeks after admission) he appeared a normal man save for slight deafness and the complaint of "coming all over of a shake" when he heard a gun fired He moved and spoke naturally and his spirits were excellent He had no recollection of telling me his forgotten experiences under hypnosis, but he could now recall all that he had told me and more His loss of memory had wholly disappeared save in reference to the two days' wandering which followed the first occasion of burial Under hypnosis to-day he recalled that he spent those days wandering over open country with Lance Corporal ——, that they fed during the first day mainly on potatoes which were cooked for them in a farm by a woman and her husband, that they spent that night in the open, and that they found the French on the following day

He was transferred to-day to a hospital in England

Stupor

CASE 7 (Case number 63) —Private ——, aged 29, admitted into a base hospital and seen by me on the following day He was in a condition of pronounced stupor and had to be repeatedly roused from his apparently dazed condition in order to obtain his attention He could not recall his name, regiment or age He could neither write nor read words, he could name a few letters in very large type, but was liable to confusion Twice he said "water," "comrade," and then made a gesticulation of falling He was not deaf He agreed that a shell came He complained by gesture that he had pains in the forehead His gait was normal but he could not hold his hands out for many seconds without dropping them His patellar reflexes were brisk, his pupils reacted to light normally (Cutaneous sensibility not examined.)

Four days later his condition was only slightly better He had never spoken voluntarily, he was still unable to give his name but he was more readily attentive and replied "Yes" when asked if his name was —— With great effort and after much encouragement he wrote his name Again he complained, by gesticulation of severe headache

On the following day he could give me voicelessly the names of his two children He could still only read capital letters, but once more confused some of them He could not read aloud the figure 2 but could express its meaning by holding up his two fingers The next day he showed me his wife's photograph and with great effort syllable by syllable of his own accord gave me her name

A week after admission, his speech being still extremely limited and laboured and his memory of his recent experiences being still unobtainable, I subjected him to hypnosis, in which state, after much persuasion I induced him to talk about the events that had preceded the onset of his disorder He became very excited, breathed rapidly and made gestures showing the positions of the various items in the scenes he began to describe evidently visualising them vividly Hoarsely and breathlessly he explained in broken sentences how he was in the trenches and was sent to draw water at a pump when two or three shells burst over him, knocking him down This seeming a sufficient recovery on the first trial of hypnosis, he was awakened after certain post-hypnotic suggestions had been made to him, these he carried out He could repeat all he had told me under hypnosis speaking with considerable effort but with far less emotion and with enormously improved fluency and speed He could now give me his home address

Two days later, no further recovery of memory having occurred, I hypnotised him a second time, whereupon he described to me how, after being shelled, he lay on the ground in a dazed condition for some minutes, and how he then rose, picked up the bottles, and returned to the trenches, after which he "lost all sense and reason" He said, "I remember my mates telling me I was silly It was time for us to be relieved at the trenches, but I don't know how I went back with the boys, it was only a short distance to the village After that I remember nothing until you tried to make me speak" By further persuasion I elicited from him full details of the still forgotten interval, how he got back to his billet, took off his equipment, then lay down, and was wrapped in a blanket by one of his comrades "I remember going to the doctors, complaining of a bad headache I remember a jolting ride, and then I lay on a blanket in a big room full of men" By now he recalled the whole of his forgotten experiences, including the train journey down to the base

On the following day, being asked whether he did not feel himself again, he complained that he still wrote with very great difficulty and inaccuracy, that his speech, like his writing was not so rapid as normally His writing was certainly very laboured Consequently he had not liked to write home to his wife, but had been obtaining the services of a fellow patient for the purpose Under hypnosis his speech and writing were restored to their normal rate He learned to say with astonishing rapidity the verses, "Peter Piper picked a peck," &c, and was induced to write a letter to his wife at very good speed Post-hypnotic suggestions that on waking he would repeat these verses and write the same letter to his wife, and that he would hereafter write and speak with normal ease and rapidity, were absolutely successful

He was discharged two days later to a hospital in England and has since been passed for foreign service, occasional severe headache preventing him from active service in the field

General Remarks

Malingering—After nine months of special work in France and Belgium upon these disorders I have not the slightest hesitation in maintaining the genuineness of the cases above described The condition of hemi hypalgesia in Case 4 and the peculiar disturbances of sensibility mentioned in describing Case 5 have occurred in numerous other cases which have come under my observation The persistence of the spasmodic movements during sleep, their confinement to the sartorii, and the spastic condition of the legs in Case 5 also point to the absence of malingering So, too, do the severe constipation and retention of urine in Case 6 and the mode of progress towards recovery in Case 7

Condition before hypnosis—Although these cases have been described under headings which are determined by the most prominent disorders characterising them, it will be seen that certain disturbances are common to all, e.g, amnesia, varying from complete obliterations of the past to obliviscence of the scenes occasioning and following the shock, severe headache, and a mental condition varying from slight depression to severe stupor Disturbances of sensation and movement might be absent or, if present, were extremely variable Mutism, when present, had begun to disappear by the time hypnosis was attempted The stuporose condition was also disappearing by that time

When in a state of severe stupor all that could be obtained from the patient were remarks as to the shelling, as if his condition were due to the concentration of the patient's attention on the scenes which had upset him A little later an alternation of states often occurred One subject, for example, whispered to me, "Did you see that one? It went up on top" "What now?" I asked 'They keep going over," he replied. Unable to catch a remark, I asked, "What did you say?'

"I was talking to my mate" was the reply To my question "What were you saying?" he answered "Get rifles" This patient could be made to realise he was in hospital, but explained his inconsistent behaviour by the remark, "Can't help it I see 'em and hear 'em (the shells)"

In another case of apparent depression accompanied by deafness the latter symptom was found to be very largely due to inattention, his thoughts repeatedly flying to the trenches For a few minutes his attention could be gained, then his answers became absurd, the question "How old are you?" for example receiving the reply, "It passed my right ear" He would often ask me to speak louder when on the point of lapsing into thoughts of trench life In another case the alternation of states was so marked that on being unduly pressed for his thoughts when in a stuporose condition he assumed an attitude of hostility, rushing about the room with an imaginary rifle in his hands

Indeed, in all these cases whenever the memories dissociated from the normal personality were revived they were accompanied by an outburst of emotion, sometimes of frenzy, but generally of fear But in the cases described in this communication it was impossible without the help of hypnosis to obtain any revival of the lost memory Not even in dreams did it return. When such patients endeavoured to think of their forgotten experiences their headache became so severe as to prevent them from further effort When, if mute, they endeavoured to talk they complained generally of a pain in the throat, usually as if someone were gripping their thyroid cartilage

Condition during hypnosis—These pains appear to constitute the guardians of the condition of amnesia, any effort on the patient's part to break down the latter generally resulted in increased severity of the former It is, therefore, not surprising that pains frequently caused the patient to wake from hypnosis as soon as his attention was directed to his forgotten memories or when attempts were made to get him to speak Experience soon taught me that before I could induce free speech during hypnosis I must first dispel, by suggestion, all pain, soreness, or discomfort in the throat, and that before I could hope to revive lost memories during hypnosis I must first suggest the disappearance of headache and prevent the recurrence of any trace of it Even then there was frequently a strong disinclination to talk of the forgotten periods, as if they were being actively inhibited or "suppressed' rather than as if they had been passively "dissociated' When at length this reluctance was overcome the attitude of the patient often changed from depression to excitement, especially when the former condition had been well marked His pulse and respiration increased in frequency, he sweated profusely, and not infrequently showed clear evidence of living again through the scenes which were coming vividly to his mind

Condition after hypnosis—There usually followed a distinct change in the attitude of the patient His previous despondency vanished, he was delighted at having recovered his speech and memory Sometimes the change was so well marked as to appear like an alteration of personality In the case of one patient, for example, who had recovered considerably from stupor and mutism before I saw him, but who was still in a miserably lacrymose and dejected condition, I was able to cure his amnesia by means of hypnosis and to bring about the following changes, the account of which I extract from my note book

During hypnosis I suggested that on waking he would remember the past, forget that he had already told it me, and say that he felt quite fit and ready for a job of work in the hospital This he did, but talking in the same semi stuporose manner as before hypnosis Just as he was going out of the door I clapped my hand on his shoulder and asked, "Now what about those shells, D——?" His manner almost instantaneously changed His voice and way of speaking seemed as if of another person He brightened up as he rattled off a quite coherent and interesting story He bore himself like a good soldier, and returned to his ward, where everyone was amazed at his changed demeanour, and he proclaimed himself quite well

In the four cases described at length in this communication similar but less marked changes followed the awakening from hypnosis Increase in the size of the pupils was also noted in one of them, while in two other cases, not here recorded, the pupils, widely dilated before, now returned to a normal size In another case the patient said that before his memory had been restored to him through hypnosis his mind was continually "rambling" from one train of thought to another, whereas afterwards it "worked as usual" Other post hypnotic changes also occurred in which previous suggestion (during hypnosis) played no direct part The best marked of these was the disappearance of disturbances of cutaneous sensibility (Cases 4 and 5)

The results of hypnotic treatment—At the time of writing[2] I have hypnotised, or attempted to hypnotise, 23 cases of shell shock The conditions under which I worked were such that no patient was subjected to further hypnotic treatment unless he proved readily hypnotisable on the first trial The immediate results may be summarised —

(1) Apparently complete cures	26	per cent
(2) Distinct improvement	26	,
(3) Failure to hypnotise	35	,,
(4) No improvement after hypnosis	13	,,

The patients included under (4) were (*a*) two afflicted with deaf mutism, to whom suggestions of hypnosis could consequently be conveyed only in writing and could not readily be enforced during hypnosis by such relatively ineffective method of communication, and (*b*) one suffering rather from aphonia and incoördination of speech movements than from true mutism, who I suspect artificially maintained, at least in some degree, his symptoms and the hypnotic state into which he seemed to pass

A point of greater interest, however, is the further history of the apparent cures Even in France I had ample evidence to show me that recoveries after hypnosis need not be immediately complete or permanent One case, for example (not included under (1) in the above table), is perhaps worth recording at length

Case 8 (Case number 272) —Rifleman —— aged 30 who was admitted, four days before my first visit to him at the base, into a casualty clearing station, 'having the air of an imbecile and having wandered about in an aimless fashion not knowing where he is or what he is doing, but having a fair knowledge of recent events' On his way down to the base he had passed through another casualty clearing station, where he was described as "remaining absolutely speechless and terrified on being questioned."

---

[2] Since this was written I have had opportunities of practising hypnosis on several other cases

On examination I found him in a state of evident terror, but after persuasion he talked (in a faint voice) of his wife, home and previous occupation. He gave the present month as October (actually August), and said that he had been out in France two months (actually 12). He had no recollection of getting to this hospital. He last remembered himself at the trenches, the scenes in which he described with obvious emotion. His mind then wandered to his wife whom he pictured sewing When not actually terrified, he was in a miserably depressed condition

Under hypnosis he remembered going into a dug out after running away from the shells falling in the trenches but he could not recall anything later He could be made to talk in a loud voice, but he awoke spontaneously from hypnosis, with little change save an improvement in his headache

On the following day, when hypnotised, he gave me correctly the present month and the month of his arrival in France, and could give me the names of two towns, Y—— and B——, close to the firing line. On waking he believed himself to be at the latter of these towns He was again much worried about his wife mentioning her christian name and the words "no work." I got him to write a letter to her, the first he had sent her since his illness It was the ordinary letter of a soldier, containing no reference to his condition

The next day he was considerably changed in behaviour and was now active busily engaged in making the beds in the ward. But he was mute (possibly affected by a case of mutism then in the same ward) Under hypnosis his speech returned, and he recalled the immediate cause of his condition, his visit to a horse show at B—— with a man named R——, and his return towards his billet at night when shells began to fall on B—— railway station and something hit his back. He said that he ran to a shed not very far from his billet He was found hiding in the shed that night and was brought into "a sort of hospital" in a motor ambulance After he awoke from hypnosis his power of speech was maintained, but it failed whenever he was asked about the incidents described above After much effort it returned, but his voice was weak and again mutism followed when he was pressed about these incidents

The following morning he awoke, speaking in a normal voice. His neighbour said that he nudged him asking, "Is it me that's talking?" To-day the change in his appearance was still more striking, he was now quite garrulous, and seemed a very intelligent agreeable fellow, whereas before he was depressed and dull His memory was now far more reliable and complete as to his past history

At Y—— he had been in the trenches up to a week before the onset of his present condition He was now able to give me his reasons for worrying about his wife He had only married just before crossing to France, and some months ago he had heard that she was pregnant He had been troubled with the feeling that she was in money difficulties and kept thinking of the experience of a friend whose wife had lost her first baby at birth

Since his return to England this patient has written to me that his recovery has been permanent and, save for occasional headaches complete He is now serving in his reserve battalion

In another case, one of mutism (also excluded from the "apparently complete cures"), hypnosis was followed by a sufficiently complete recovery of speech for the patient to tell me his regimental number, but an hour later he was found to be again quite mute and "as dismal as ever" In this case, however, rehypnosis proved futile He could not even be induced to write during hypnosis, although he had written out his history earlier In my notes he is reported as being "too dazed and unintelligent during hypnosis, bordering, I fancy, on a hysterical attack (he had had two 'fits' while in the trenches), frequent tremors and clonus of arms"

Yet another patient completely recovered from his depression and amnesia at the first trial of hypnotic treatment, but was accidentally discharged from hospital on the following day by a medical officer who, judging from the patient's appearance and in ignorance of his past condition, pronounced him fit for duty Two days later he was re admitted to hospital in the same stuporose, depressed, lacrymose state as before

These and other cases show that hypnosis is of relatively little value when the condition of stupor is too profound, and that any subsequent worry (e g, over home affairs) or terror (e g, of scenes of the trenches or of returning to the front) is apt to induce a relapse Accordingly, nearly all the severer cases of shock which I have seen have, at my advice been sent to England

The value of hypnotic treatment—Despite the slow progress just recorded in certain cases, I have not the least doubt that the hypnotic treatment which these and other cases received here invariably proved of great assistance towards recovery, and would have proved of still greater value if it could have been occasionally repeated later It may be argued that mutism, rhythmical spasms, anæsthesiæ, and similar purely "functional" disturbances disappear after a time without specific treatment But no one who has witnessed the unfeigned delight with which these patients, on waking from hypnosis, hail their recovery from such disorders can have any hesitation as to the impetus thus given towards a final cure More especially is this the case in regard to the restoration of lost memories Enough has been already said here about the striking changes in temperament, thought, and behaviour which follow on recovery from the amnesia

To go further into the subject would involve detailed consideration of the rationale of hypnosis in such cases, but this can be more conveniently postponed to a separate communication devoted to the psychology of shell shock generally Nevertheless, surely this much may be taken for granted here, that the restoration to the normal self of the memories of scenes at one time dominant, now inhibited, and later tending to find occasional relief in abnormal states of consciousness or in disguised modes of expression—such restoration of past emotional scenes constitutes a first step towards obtaining that volitional control over them which the individual must finally acquire if he is to be healed Thus the minimal value that can be claimed for hypnosis in the treatment of shock cases consists in the preparation and facilitation of the path towards a complete recovery

---

BRITISH FIRE PREVENTION COMMITTEE —The activities of the British Fire Prevention Committee for the year just brought to a close include the preparation and free issue of a large number of public "fire warnings" in the form of posters, circular letters, or as notices Special notices were issued for hospitals, convalescent homes, refugee hostels schools billets, factories, and farms, whilst air craft hazards were dealt with on general lines The total issue exceeded 250 000 At the outbreak of the war a special fire survey force of 100 surveyors was formed to undertake at short notice, and in an honorary capacity any fire surveys required by the Government The results of the work have been far reaching The greater care taken by the public to prevent outbreaks of fire by sensible and inexpensive precautionary measures has been most marked, as also the effort to meet fires with organised self help and simple hand fire appliances A material reduction of the annual fire loss during the war has been achieved The loss of life from fire has been reduced, and large quantities of produce and goods important to the conduct of the war have been thereby preserved

THE ADVANTAGES OF WARM ANÆSTHETIC VAPOURS, AND AN APPARATUS FOR THEIR ADMINISTRATION

BY FRANCIS E. SHIPWAY, M.A., M.D. CANTAB.,
HONORARY ANÆSTHETIST TO GUY'S HOSPITAL, TO THE KING GEORGE HOSPITAL, ETC.

"Open ether" suffers from certain defects which detract much from its value and cannot be ignored. To avoid misunderstanding it is well to state at once that by this term is meant that method of anæsthesia by which ether is dropped (more or less) continuously on to some fabric spread over a mask which is so closely applied to the face that the whole of the air current, in both directions, passes through the fabric. Its chief defect is the lowering of the temperature of the inhaled mixture of air and ether due to the coldness produced by the evaporation of ether and the tendency to the formation of frost on the mask. This lowering of temperature is progressive, and may continue until the inhaled vapour may be 30°–40°F. below the temperature of the room. Cunningham and Anderson, indeed, have stated that in a room at 80°F. with the "open" method a 2.1 per cent. ether vapour reduces the temperature of the inhalations to 30°F., a 5.4 per cent. vapour to 9°F. If these figures as applied to the "open" method described above are correct, they are startling, but in any case every anæsthetist is aware that the vapour inhaled is chilled and that the temperature within the mask often reaches a low level. Evidence is adduced in this paper to show that the inhalation of such a vapour, besides having other consequences, reduces the body temperature to an extent which may no doubt be of comparatively small importance in many surgical operations, but in a great number, and especially in unfavourable cases where any adverse factor is of moment, must lessen the patient's chances of recovery and may increase the risk of pulmonary complications.

It is, further, a practical disadvantage of the method that saturation of the fabric and freezing of the moisture of the breath interfere with the free intake of anæsthetic and therefore with the smoothness of anæsthesia, and sometimes with a proper depth of anæsthesia. It is probably for this reason that some anæsthetists profess that they cannot obtain in all cases good relaxation with "open ether," and are loth to abandon the Clover.

It is only within recent years that scientific study has been given to the warming of anæsthetic vapours. It is true that it is one of the advantages of the Clover and other rebreathing inhalers that the patient inspires a warm vapour, and it has been asserted for this reason that Clover and the anæsthetists of his day recognised the importance of this subject, but it is clear from a study of their original articles that this is a mistaken idea if care be taken to distinguish between the measures which were employed to warm ether vapour in order to aid the administrator and the efforts which are made by the latter day anæsthetist in order to benefit the patient. THE LANCET,[*] in describing Clover's apparatus as "the only one entirely approved by the Chloroform Committee of the Royal Medical and Chirurgical Society," says nothing of the temperature of the vapour. Clover, in describing his double current inhaler,[2] says that "the supply of ether vapour" is "rendered more uniform by attention to its temperature which was kept within limits by causing the expired air to pass through the ether vessel in a kind of worm"; again,[3] he provided in his second model "a reservoir of water to prevent the temperature of the ether becoming too low." In his account of his portable regulating inhaler[4] he also discussed this subject and decided to use a water chamber surrounding the inhaler as the most convenient plan. Hawksley[5] introduced an inhaler at about the same time, the ether bottle of which was "half immersed in water heated to 100° F. in order to promote a more rapid and equable evaporation of the ether." No mention is made in any of these articles, nor in the description of the Ormsby inhaler (1877) of the value of warmed anæsthetic vapours to the patient, and no attention is given to this subject in the latest editions of the works of Sir Frederic Hewitt and Dr. Dudley Buxton. It is clear that in nearly all cases the patient did inspire a warm vapour, for he breathed backwards and forwards into a bag and in the early days it was a common practice to wring a sponge or cloth out of boiling water, but it is equally clear that what Clover, Hawksley, and the others aimed at was the prevention of excessive cooling of the ether or actual freezing of the sponge which would interfere with the supply of the anæsthetic. It is interesting, on the other hand, to find in Dr. Foy's "Anæsthetics Ancient and Modern" an illustration (p. 141) of a nitrous oxide apparatus, made by Messrs. Arnold, in which the agent is warmed by being passed through a hot water chamber, and the author tells me in a private communication that it is just possible that the above facts were familiar to the makers and influenced their design of the inhaler.

Anæsthetists have from time to time warmed their agents, but it was the advent of "open ether," with its prominent defects, that induced some specialists in this branch of surgery, notably Gwathmey,[6] to study fully the subject of the warming of anæsthetic vapours. Various devices have been already used in order to remedy these defects—e.g., cones of different patterns and the Ferguson mask—but they have never been wholly satisfactory, for they are really semi-open inhalers, and if they impart a certain amount of warmth and save a certain amount of anæsthetic they introduce at the same time an undesirable degree of rebreathing. Gwathmey[6] and Davis[7] attacked the problem on scientific lines, preserving the open character of the anæsthesia and investigating the effect of warm vapours on patients and on animals. As a result of their researches they have reached some important conclusions and have made a notable advance in the science of anæsthesia. Coburn,[8] Pinneo,[9] and others have introduced apparatus for delivering warm vapour, in addition to the names already mentioned, that of the former being applicable to either "open" or closed ether. The anæsthetists who have devoted themselves to the study of nitrous oxide and oxygen for use in general surgery, the pioneer of whom is Teter,[10] are almost unanimous in advocating the warming of these gases; their example has been followed by my colleague, H. M. Page, who has also added a simple warming chamber to Crile's nasal tubes.

Although the case for warmed vapours has been subjected to a certain amount of criticism,[11] which seems to be ill founded, the evidence on which it is based is too strong to be upset Experimental and clinical observations of Davis and Gwathmey are mutually confirmatory The latter[6] investigated this subject fully in animals, using chiefly chloroform and nitrous oxide and oxygen, administering them at room temperature and at a temperature of 100° F, and noting their effect under these conditions with reference to such questions as safety and maintenance of body temperature He found that these anæsthetics are much safer when administered at blood temperature—e g, whereas it took 6 57 minutes on the average to kill 16 animals with chloroform at room temperature, it took 20 35 minutes to kill 17 animals with warm chloroform. Similar results were obtained with nitrous oxide and oxygen, death occurring more quickly when the gases were administered at room temperature, the action of the heart and the respiration were also more irregular Nitrous oxide and oxygen at a temperature of 33°–34° F caused death in a much shorter time. Fewer experiments were made with ether, but enough to convince Gwathmey that warm ether vapour is twice as safe as cold He concludes that all anæsthetics heated to the temperature of the blood are increased in value as regards life without their anæsthetic effects being decreased

---

[*] THE LANCET, Dec. 17th, 1864, p. 693.

As regards the maintenance of body temperature Gwathmey's conclusions have been confirmed by the work of Davis,[7] whose observations have a particular interest for the anæsthetist who uses 'open ether ' It has long been known from the investigations of Kappeler, Allen, and others that the temperature of the anæsthetised person falls, due chiefly to diminished oxidation and to the interference with the heat regulating centres The fall is greater in proportion as the operation is protracted, or large surfaces of the body are exposed, or the loss of blood is considerable, and may be of great importance in feeble, very young, or elderly patients, particularly if no special precautions have been taken to cover up all parts outside the operation area. Davis supports the work of the earlier investigators, and points out that the method of anæsthesia has more influence upon the maintenance of the body temperature than is commonly supposed to be the case He found that in 140 patients anæsthetised by the "open" method there was an average loss of temperature of 1 02° F, as against an average loss of 0 29° F in 26 patients anæsthetised by warm vapour, the temperature was taken by the rectum immediately before and after anæsthesia. In 5 cases in which a large surface of the body was exposed, the anæsthetic being "open ether," the average loss was 1 98° F, in 6 cases under similar conditions, except that a warm vapour was given, the average loss was 0 77° F There was a loss of 2 99 F after appendicectomy and removal of one ovary in a patient who during 1¼ hours lay on a cold table the abdomen having been flushed with fluids and covered with wet towels, these conditions are to be found less frequently to day, but they still occur on a smaller scale in a certain number of abdominal operations It is a good plan to change towels which have become wet with saline or lotion during a protracted operation, for if allowed to remain they have the same evil effect as the towels wrung out of antiseptic which were formerly used to surround the area of operation These results of Davis are important, and he concludes from his observations and from experiments on animals that warming of ether vapour before inhalation will prevent loss of body temperature, or may actually increase it in a degree proportionate to the temperature of the vapour and also to that of the operating-room. Undue elevation of the temperature from this source is injurious With regard to the effect of morphine, he states that the previous administration of this drug does not greatly increase the loss of body temperature caused by ether Excessive application of heat to an individual under morphine will lessen the usual loss of heat, the additional administration of ether in these circumstances may lead to a rise in body temperature rather than to the expected fall

Davis raises a subject of some controversy when he discusses the optimum temperature of the operating room for he favours a temperature of 80° F or over, showing, as is only to be expected, that the higher the temperature the less is the loss of body heat It is doubtful, however, whether his view will be generally accepted High room temperatures lead to sweating and exhaustion, not only of those taking part in the operation—a matter of some importance in hospital work with a lengthy list of operations—but of the patient Sweating is particularly harmful to the patient, both because he loses fluid and because he is chilled by contact with wet garments The most rational procedure would seem to be to maintain a moderate temperature of 65°–70° F, to keep the patient warm and dry, and to prevent as far as possible the loss of body heat by the use of warm anæsthetic vapours Nearly all patients complain of feeling chilled on recovery from an anæsthetic, and the change from the warmth of the operating-room to the lower temperature of the ward or bedroom, especially if cold passages have to be traversed, is a greater tax on the recuperative powers if the thermometer in the former has stood at 80° F or higher Dastre stated that the temperature falls more rapidly with ether than with chloroform, but Davis finds that chloroform produces a loss of body heat approximately equal to that of ether

In addition to the defects of "open ether' already described, the waste of ether is a disadvantage, its extent depends upon various factors, and is unavoidable if this method is strictly followed. Another disadvantage is the diffusion of much vapour into the room, to the discomfort of everybody present The last of the objections to "open ether" which it is proposed to discuss has been raised by Yandell Henderson[12] It is that hyperpnœa may be produced, followed by acapnia which, he says, is the cause of shock Henderson believes that this sequence of events often occurs where a too "open" method is used, where, on the other hand, a considerable degree of rebreathing is allowed and the anæsthesia is in reality a good "closed ' ether—e g, where a towel is used in the form of a cone—the patient comes through the operation with excellent colour, warm dry skin, quiet breathing, and strong pulse He advocates strongly a return to "closed' ether, and owing to the vigour of his pleading and the known importance of carbon dioxide, "open ether" is losing some of its popularity in the country of its origin. It has not been shown, however, that the acapnia theory has gained universal acceptance or even received that measure of support which must be forthcoming before Henderson's conclusions can be allowed to dominate anæsthetic practice Whilst it is true that acapnia may, or does, occur under certain conditions of ether anæsthesia, it would be an exaggeration to say that it occurs commonly in English practice or to such a degree that it is of serious or even of any import In fact, "open ether," not being open, compels a certain amount of carbon dioxide retention (which is kept within reasonable limits), and as it is usually preceded by an injection of morphine which depresses the respiratory centre, in some cases markedly, so that there is a difficulty in obtaining deep anæsthesia except after some delay, it is evident that hyperpnœa is an uncommon phenomenon The danger of acapnia is not so likely to arise as that of excessive retention of carbon dioxide, for the anæsthetist wishing to prevent the wastage of ether is tempted to use some device to overcome it, with the result that the "open" becomes to all intents and purposes a "closed" ether, with a corresponding deterioration in the quality of the anæsthesia The patient is a little cyanosed, there is some congestion, and breathing is a little hurried or even laboured The chief advantage of the "open" method—viz , free interchange of air—has been lost

We see then that, however skilfully administered, "open ether" places the anæsthetist in a predicament He must choose one of three courses either he must submit to the defects and difficulties of this method, or he must give it up entirely and revert to a rebreathing method, or he must endeavour to find a method which is an improvement upon both If we admit the views of Yandell Henderson, and agree at the same time that "open ether" is economical neither of body heat nor of anæsthetic, we shall have to follow his advice to restore "closed" ether to its former position This solution seems to be entirely wrong, for his views are non proven and our aim is progress, we have only just emerged from darkness and found light, and it would be folly to throw away the advance gained in recent years We can take yet another step forward by adopting an improved "open" method—viz , "warm vapour anæsthesia," by which is meant a system which applies to ether (or mixtures of chloroform and ether), the principle of the Junker, with the addition that the vapour is warmed and is of suitable concentration to be used in general surgery The idea of using ether in a Junker bottle is not new, for Tyrrell[13] in 1897 showed a method of adding ether vapour during chloroform administration, calling it a 'double bottle method" Stock[14] also utilised this idea, and determined the percentages of ether and chloroform which he was able to administer, and Apperly[15] introduced a simple and practical apparatus for vaporising ether for use in nose and throat operations, but none of these apparatus deliver a warm vapour or were intended for the maintenance of ether anæsthesia in general surgery

Warm vapour anæsthesia has been used for some years in America, my own experience of it dates from October, 1914, when I was able to procure what I think is a suitable apparatus It is an "open" method in which the patient breathes *from* an atmosphere of warm ether vapour and air instead of inhaling cold vapour *through* a fabric It preserves the best points of "open ether"—viz , simplicity, free respiratory exchange, and equable dosage It is economical of ether, since the patient receives at each inspiration a suitably adjusted and practically constant percentage, no ether is lost by evaporation and very little during expiration It solves partially for those anæsthetists who do not use intratracheal insufflation the difficulties of anæsthesia in patients lying in awkward positions. Further, it enables the anæsthetist to be more out of the way of the surgeon and to be less hampered in his work than when he is using a drop bottle

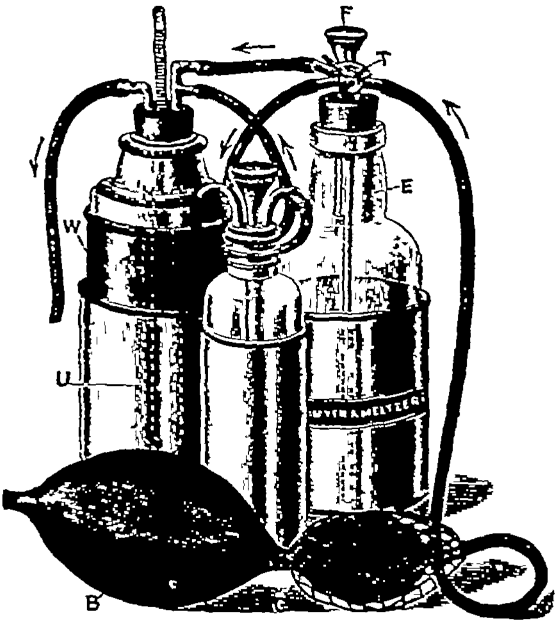
In addition to these advantages, warm vapours are more pleasant to inhale and are more readily absorbed by the blood, so that anæsthesia is induced more quickly and more quietly and can be made to reach a more profound depth in a short time Teter[16] found that of 40 women who inhaled warm nitrous oxide (90° F) many were unconscious after two or three breaths, whilst if cold nitrous oxide were given the majority were conscious up to the tenth, and some up to the twentieth, breath. Ether vapour when warmed is less disagreeable to inhale and is less irritating, so that it causes less secretion of mucus and saliva. Nausea and vomiting are stated to occur not so frequently, but large numbers of cases must be compared before this claim can be considered to have been definitely proved My own impression is that vomiting is slightly less, but "open ether" has given us very good results upon which it will be hard to improve Certainly smaller doses of atropine can be used Another advantage of the decreased irritating effect is that muscular spasm and congestion of the upper air passages are considerably diminished Breathing is calmer and slower and very similar to the chloroform type, so that it is easier to secure quiet anæsthesia and good relaxation in difficult subjects I find that an 'airway" is seldom needed, either nasal respiration is adequate or a mouth prop which separates the jaws to a slight extent, secures the desired type of breathing There is not the same objection to the use of an artificial airway as in "open ether," where it introduces a cold vapour directly into and on to the laryngeal opening, increasing the risk of bronchitis, and I believe the liability to laryngeal spasm

I wish to lay stress upon the superiority in the type of anæsthesia produced by a warm vapour, because my experience with this method has now been sufficiently large for me to speak with confidence, and because ease of breathing and the elimination of the asphyxial factor resulting from even a slight degree of obstruction are of such importance in the prevention of shock Experience teaches this lesson daily, and intratracheal insufflation has proved conclusively that if there is one cardinal principle of anæsthesia which should be emphasised it is the value of a free airway and of complete *oxygenation*.[17] For these reasons, and because the loss of body heat is less with warm vapours, shock should be, and in my experience certainly is, diminished Patients recover perhaps a little more quickly, this, again, is only to be expected, and Gwathmey's experiments point to the same conclusion, although their number is too small to be conclusive

It seems likely that lung complications will be less frequent, not only because the loss of body heat is smaller and the patient's powers of resistance are therefore better conserved, but because the respiratory passages are not so liable to become invaded by mucus or to become infected owing to chilling It may be that the warm ether of this method will have a wider field of usefulness, but it would be well at a time when there is a tendency to give ether to patients usually considered unsuitable for this anæsthetic, and a certain number of avoidable cases of bronchitis occur every year, to proceed with caution in this direction

Since I have been using this method it has struck me very forcibly how much the idea of warming anæsthetic vapours, especially ether, appeals to onlookers, who cannot have failed to notice the low temperatures produced by the "open" method, and how wrong we have been, and still are with our present knowledge, in allowing our patients to inhale these cold atmospheres It seems undeniable that this position is no longer justified We must teach the principle of warm vapour anæsthesia and turn our energies to the development of this method along scientific lines and to the production of simple and practical apparatus The administration of warm nitrous oxide and oxygen does not come within the scope of this paper

The apparatus which I use consists of four principal parts—viz. B, A hand bellows of large capacity, E, an ether bottle, C a Junker chloroform bottle, and W, a warming chamber (vacuum flask) E, C, and W are contained in metal stands connected together, that of C being detachable, and as well as that of E being of larger diameter than their respective bottles, so that they act as water jackets to prevent excessive cooling of the anæsthetic



In the cork of E are (1) An efferent tube, (2) a filling funnel (F), and (3) a regulating tap (T), the long limb of which is plunged into the ether, perforations at the end of this limb break up the air current and prevent splashing of the ether To the proximal of the two short limbs of T is attached the hand bellows, the distal is connected by rubber tubing with the afferent tube of C The efferent tubes of E and of C are connected by tubing to two branches on the afferent limb of U, which is a metal U piece immersed in the warm water of W The delivery tube of U carries 30 inches of rubber tubing

By regulating the lever of T air can be pumped (a) through E, (b) through C, or (c) in varying proportions through E and C at the same time, so that the vapour of ether of chloroform, or of mixtures of the two can be given The anæsthetist will find it a great convenience if he is using chloroform and the colour is pallid or the breathing weak, to be able to add ether or substitute it entirely for a time A very strong ether vapour can be obtained and can be made still stronger by placing warm water in the jacket The hand bellows is of such a size that it fills the hand comfortably, and continuous pumping is not wearisome By squeezing it regularly with inspiration the anæsthetist soon acquires the habit of delivering a practically uniform dosage He has two means of altering the strength of the vapour, one by regulation of the tap, the other by varying the vigour of his squeezing Regularity of administration means evenness of anæsthesia, and this means an anæsthesia which can be kept lighter and yet efficient A foot-bellows can be used if it is desired to give ether for nose or throat cases, as suggested by Stock,[11] or can be substituted for the hand bellows in all cases, this particular pattern gives a continuous stream of air, and is therefore of advantage in that the anæsthetic is supplied in a more constant percentage than is possible with a hand bellows There are points for and against its use, and I have decided to employ it only in the special cases mentioned if intratracheal insufflation is not required

About 6 or 8 ounces of ether should be placed in E, to empty it remove the stopper of F and slip off the tubing from the ether efferent tube, which then can be used as an outlet If chloroform is not wanted, C and its jacket can be detached altogether if desired, the distal limb of T is then connected with the free branch of U In this case all the air can be pumped through E, or any part of it, the rest going on to W It has been my aim to make the apparatus as simple as possible, it is efficient and easy to use The anæsthetist is independent of electric or other systems of heating, and can depend upon the temperature of the vapour remaining remarkably constant for a considerable period, it is very seldom necessary to change the water in the flask

Anæsthesia is induced in any way thought desirable My own plan is to give a preliminary injection of atropine, with or without morphine and scopolamine, and to induce with chloroform or a mixture, using a drop bottle or the apparatus, in the latter case the end of the delivery tube is placed under the mask, which holds in its place, or passed through the domette covering it It should not be attached to any connexion or metal tube, or much of the heat will be abstracted from the vapour, ether vapour quickly picks up and quickly loses heat Beginning with chloroform, after a little time a mixture weak in ether can be given, then less chloroform and more ether, until finally pure ether is being administered. If induction is accompanied with struggling or with raising of the head and shoulders it is advisable to use a drop bottle until quiet is obtained, the vapour method can then be used again In whatever way induction is accomplished, when the time has arrived for the introduction of the warm ether vapour a flannel pad with opening for the nose and mouth is laid upon the face, the end of the tube is slipped under the pad, and a Schimmelbusch mask with two layers of domette is placed on top of it For children or weakly patients one layer of domette is sufficient Ether is pumped in cautiously, beginning with a weak vapour and gradually increasing the strength as tolerance is established, until the proper degree of anæsthesia is obtained Occasionally it may be necessary to pump continuously for a short time, but, as already stated, regular pumping with or just before inspiration is best For mouth cases the tube is placed in a curved metal holder which rests between the teeth, or is attached to a soft rubber catheter which is passed down the nose to the edge of the soft palate

The *longest* anæsthesia in my series of cases, which includes practically every operation, lasted 3 hours and 22 minutes, the operation being for removal of a malignant growth of the bowel from a young woman who had lost 3 stones in weight, was toxic and anæmic from malnutrition, 6 ounces of ether were used, the average temperature of the vapour being 86° F This was a smaller consumption than usual, the patient being an easy subject to anæsthetise, but I feel that "*open ether*" could not have given me such a good result nor such a good recovery as was made, and I doubt very much whether it would have been wise to give a cold vapour, especially to this patient, for such a long abdominal operation

The details of the following cases give a rough idea of the amount of ether used in different patients and operations —

1 *F*, 29 vigorous, alcoholic Morphine gr 1/6, scopolamine gr 1/150, atropine gr 1/120. Struggling during induction with C E Appendicectomy, rectus incision Deep anæsthesia, especially for suturing abdominal wall 50 minutes, 4 ounces of ether

2 M, 47, big powerful navvy, thick neck, double chin Morphine, &c, as in Case 1 Induction with C E and "open ether", rather violent struggling, quiet easy anæsthesia Plating left tibia 46 minutes, 4 ounces 2 drachms of ether

3 M., 16, tall, weedy Morphine gr 1/8, atropine gr 1/150 A.C.E for induction Appendicectomy, followed by radical cure of left inguinal hernia 33 minutes, 2 ounces 6 drachms

4 F, 39, slight build Morphine gr 1/6 atropine gr 1/100 Induction with C E *Colectomy* Deep anæsthesia during whole operation, *patient rather resistant to* anæsthetic 1 hour 36 minutes, 5¼ ounces Condition very good at end; patient warm and dry, pulse 76, good quality A very similar result had been obtained a few days before in a young woman aged 22, colectomy, 1 hour 49 minutes, pulse at end 80 These and several other similar cases have helped to strengthen my feeling that it is a distinct advantage to warm the vapour of ether, chloroform or of mixtures of the two

5 M, 29 strong, active, intelligent nervous temperament Morphine &c, as in Case 1 Sleepy Easy induction with C E Exploration of abdomen, mid line incision, followed by appendicectomy through same incision Very difficult to obtain good relaxation at first particularly during suturing of abdominal wall, peritoneal reflexes being strong, anæsthetic pushed, no corneal reflex pupil big jaw muscles slack. 1 hour 9 minutes, just over 4 ounces of ether used

Careful tests have been made of the ether before and after use by the methods described by Finnemore[17] No aldehydes have been found on any occasion, even after air has been pumped through the ether for several hours and although peroxides were shown to be present The test for the latter impurity in the new British Pharmacopœia is very stringent, so that Finnemore says that freshly distilled ether will probably be found deficient after being kept for a month It is obvious that only very few ethers can comply with this test, and although it is theoretically desirable that peroxides should be absent, it is not always practicable, and as long as they are only present in small amount, and aldehydes are completely absent, the ether can be safely used My practice is to use the same ether *twice*, as many tests have shown me that it is only occasionally that peroxides are present after the *first case*, and then in very small amount

At what temperature should the vapour be delivered? There is no need to warm it artificially in very hot weather above the room temperature, in cold weather 85°–90° F will give good results, the higher level being better for patients who are feeble or shocked, or for operations which involve much exposure and loss of heat or much bleeding Too much heat produces sweating and flushing of the face and neck, and an unusual amount of bleeding in the wound, due to dilatation of cutaneous vessels The following observations illustrate the results that may be expected at different room temperatures, and with water at different temperatures —

	Room temperature	Water in flask	Temperature of ether vapour at end of 30 in. of rubber tubing
1	82° F	102° F	87° F
2,	75°–76°	96°	82°
3,	71°	105°	86°
5 *	67°	133°	90°

Compare with the following, and note the steady level maintained —

4	2.35 P M,	67 5° F	117° F	86° F
	2 40 ,,	68°	116°	86°
	2.45 ,,	,,	116°	87°
	2 50 ,,	,,	115°	86°
	2 55 ,,	,,	113°	86°
	3 00 ,,	,,	112°	85°
	3 50 ,,	,,	111°	85°

* This result appears to contradict No 4 but was taken after a slight alteration had been made in the apparatus which has the effect of lowering a few degrees the temperature of the vapour In other words, results 1 2 3, and 4 are not strictly accurate but serve as guides

My thanks are due to those members of the staff of Guy's Hospital who have allowed me to use notes of their cases The apparatus is made by Messrs Mayer and Meltzer, Great Portland street, W, who have taken great pains in carrying out my ideas

FLORA OF WOUNDS AND FLORA OF PUTREFACTION

By A DISTASO, D Sc,
HONORARY BACTERIOLOGIST WELSH NATIONAL MEMORIAL ASSOCIATION
FORMERLY OF L'INSTITUT PASTEUR PARIS
(From the University College, Cardiff)

IT seems established that wound infection goes through three phases —

1 *A phase of numberless microbes, amongst which B coliformis[1] are to be found* —This group of microbes has not been described as a constant finding, but that, I believe, is mainly due to the fact that the soldiers come for observation too late, and the phase is one which passes quickly (It is a pity that from the available literature it is not possible to see to what extent the B paratyphosus and paracoli group have been found in wounds and what part they play)

2 *A phase in which the B coliformis disappear and the field is occupied by the anaerobic microbes*

---

[1] When I say B coliformis I exclude the B proteus and B pyocyaneus for reasons clear to understand

of putrefaction.—B perfringens [Welchii], Sporogenes, B X of Fleming,[2] B tetani [3] and others This group has been constantly found

3 *A phase of the reduction (most probably the pathogenic flora) in which cocci (streptococci [4] and staphylococci) only are present*

The phases which I have previously described [5] as occurring in putrefaction of the intestinal wall and of the fæces were summarised as follows (*a*) A phase in which the B coliformis became predominant and very active (*b*) A phase of the anaerobic ferments B coli disappears completely and leaves the field free to the anaerobic organisms (*c*) A phase of the aerobic ferments The anaerobic ferments have now completely disappeared and instead are found cocci and microbes of the B subtilis group I also established the fact that when B proteus or B pyocyaneus was present at the beginning of the process they persisted throughout the stage of putrefaction I am of opinion that the coliform organism, described in wounds in the late phase, is one or other of these two microbes

Of great interest are the findings of A. Fleming,[6] who has worked at the anaerobic organisms of wounds He describes, amongst others, the so called "wisp bacillus" and a Gram negative anaerobic bacillus (p 642), also an anaerobic streptococcus [7] The first is the B ramosus or a member of its group The second is very probably the B fragilis Both have been described by Veillon[8] as constantly present in acute appendicitis I have frequently isolated these organisms from cases of appendicitis, and in two instances from fæces Both organisms give rise to considerable pus formation Fleming's observations are interesting, first, because these microbes seem capable of true pathogenic action, and, secondly, because I have stated my opinion that they are normal inhabitants of the human intestine, in spite of the fact that it is difficult to isolate them from fæces

It would seem to be established from what has been stated that—

1 A true putrefactive process, comparable to that which takes place *in vitro*, occurs in the wounds and that the three phases succeed each other in the wound as they do *in vitro*

2 The fact of the presence of human intestinal flora at the beginning of the wound infection shows that the soldiers are infected from *fresh human fæces*

As regards the first point, why should these same phases occur in putrefaction and in the wounds? There must certainly be some biological law which regulates the appearance and disappearance of the microbes Two hypotheses may be considered First, that there is a nutritive mechanism which regulates the phases This suggestion is without any experimental basis, because, for example, B coli thrives very well on split albumin rendered soluble by B putrificus But, notwithstanding this fact, B coli dies after a certain cycle and gives place to the putrefactive organisms The second hypothesis is that the secretion products of certain organisms are dangerous to, or possibly stimulate the appearance of, others Experiments *in vitro* do not uphold this explanation Besides, if this hypothesis be true, why should organisms die in groups? On the other hand, if we follow the process of putrefaction we see that Phases 1 and 2, above described, present a common character—the enormous activity of the predominant microbes The more active they are the more freely they produce toxins, ptomaines, &c, which, as is known, endanger their existence In fact, the duration of life of a microbe is closely related to its activity, the products of its metabolism, and the mechanism of drainage These facts and considerations of biological nature lead me to conclude that the very activity of those microbes in the different phases of putrefaction or in the process occurring in wounds brings them direct to suicide The organisms which never die in the putrefactive process or in the wounds are the streptococci which at no stage in either case exhibit much activity

As regards the second conclusion—viz, that the infection in trenches is due to fresh human fæces—I was able through the kindness of Colonel D Hepburn, R A M C (T), commanding the 3rd Western General Hospital (Professor of Anatomy, University College, Cardiff), to make some inquiries amongst wounded soldiers They all told me that the rules about defæcation are very strict, that the fæces are disinfected, but that nevertheless the men often defæcate in the open I was told that cleansing after defæcation could not always be carried out owing to lack of paper It is easy to imagine the case of a soldier who has a wound and anal pruritus Digital conveyance under these circumstances readily occurs and a complete cycle of infection is set up (It would seem to be an easy matter to distribute a small bottle of lysol solution and a sponge)

There is, from these observations, good reason to believe that either the occurrence of defæcation in the open, or inefficiency of sterilisation of fæces, or personal filth has some relation to the described bacterial flora in wounds The phases described necessarily take a certain period of time for their completion, and this is one of the reasons why specific therapy has given unsatisfactory results The sequence is still somewhat obscure and demands further investigation, but, of course, prevention of wound contamination by fæcal material ought to be aimed at

University College Cardiff.

---

[2] Fleming's B X is the B anaerobicus alcaligines which was described by De Bono in the Centralblatt für Bakteriologie vol lxii 1912, Heft 3/4

[3] B tetani has been frequently described in the wounds although no clinical evidences of tetanus may have been observed Attention may here be drawn to B putrificus filamentosus for example which morphologically closely resembles B tetani (Centr f Bakt vol lix 1911)

[4] Sir A E Wright points out that the streptococcus isolated in wounds has not the same character as the S pyogenes It has a saddle-bag shape This streptococcus is a common organism in fæces but it is not the S fæcalis In order to isolate this wound-streptococcus I proceeded to incubate fæces to the stage of putrefaction and when all other microbes had disappeared I was able to isolate on Drigalski three or four different kinds of streptococci In many cases a streptococcus was obtained which was without action on lactose This work was communicated to the Centralblatt für Bakteriologie just before the war and I am unable to say what has become of the article (See THE LANCET Oct 30th 1915, p 959)

[5] Centr f Bak vol lxii Heft 3 4

[6] THE LANCET Sept 18th 1915 p 638.

[7] This streptococcus was first isolated by Jungano from fæces and urine Owing to a printer's error it was not included in our book Les Anaerobies" (Masson Paris 1910)

[8] Les Anaerobies, Masson Paris 1910

MEMORIAL TO THE LATE MAJOR E. B STEEL, R A.M C —At Dr Steevens' Hospital on St Thomas's Day, Dec 21st, the Archbishop of Dublin dedicated a lectern placed in the chapel of the hospital by the governors and staff to the memory of Major Steel, who died on Nov 23rd 1914, from wounds received in action An obituary notice appeared in our columns (vol ii, 1914, p 1388) For several years he was a resident pupil at Dr Steevens' Hospital, and the thoroughness of his work and sterling qualities of his character endeared him to a large number of friends

THE SIMPSON LIGHT

ITS NATURE, MODE OF PRODUCTION, AND APPLICATION, WITH A PRELIMINARY NOTE ON ITS THERAPEUTIC PROPERTIES

By W DOUGLAS HARMER, M C CANTAB, F R C S ENG,
SURGEON TO THE DEPARTMENT FOR DISEASES OF THE THROAT AND NOSE, ST BARTHOLOMEW'S HOSPITAL

AND

E P CUMBERBATCH, B.M OXON, M R C P LOND,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT ST BARTHOLOMEW'S HOSPITAL.

WHAT is known as the Simpson light is the light emitted from an electric arc formed between electrodes of special composition These electrodes are made by a special process from a mixture of the ores of certain metals, the chief one being a tungstate of iron and manganese, known as *wolfram* These electrodes are the special feature of the Simpson lamp, and they confer upon the light the properties that distinguish it from that produced by the more familiar type of arc lamp, in which the electrodes are made of gas carbon

Mr Simpson, who was making a research on the affinity of rare metals for each other, noted that the light produced by the electric combustion of certain ores had "curative effects on the workmen's hands" He then proceeded to prepare from these ores electrodes suitable for combustion in an electric arc lamp This proved to be a very difficult matter, and the most suitable composition has not yet been fully determined To procure steady combustion in the arc has been the most difficult problem

Nature of the Simpson light—The Simpson light is made up of rays of two kinds 1 *Visible rays* These are the visible rays of the luminous spectrum, violet, blue, green, &c, down to red, these rays together produce white light 2 *Invisible rays* These are *heat rays* and *ultra violet rays* It is to the latter that the therapeutic properties of the light are mainly due The physical properties of the light have been investigated by Professor Burstall and Professor Horton Professor Horton reports that the arc is an "extremely powerful source of ultra violet light" This was tested by experiment A spectrum of the light, obtained by means of a quartz prism, was cast on a sheet of white paper The colours of the visible spectrum were then seen, while the ultra violet rays were rendered visible by allowing them to fall on a fluorescent screen. The violet end of the visible spectrum was thus seen merging into the fluorescent spectrum of the ultra violet rays These spectra were compared with those yielded by the light from an arc between carbon electrodes It was seen that the ultra violet light from the Simpson lamp caused a much stronger fluorescence than that from the carbon arc lamp, and that the *length* of the fluorescent spectrum was very nearly double that of the fluorescent spectrum of the carbon arc lamp The Simpson lamp, therefore, produces a more intense ultra violet light than that emitted by a carbon arc lamp, such as the Finsen lamp Further, the light ranges nearly twice as far into the ultra violet region so that some of the component rays have a shorter wave length than those produced by the carbon arc lamp Professor Horton also made comparisons between the new arc and the arc obtained under similar conditions with electrodes of other metals known to be good as sources of ultra violet light The metals used were aluminium, zinc, and cadmium, but in every case the radiation from the new arc was considerably more powerful

The light from the Simpson lamp has, therefore, two claims for clinical investigation one by reason of its greater richness in ultra violet rays, the other by reason of the presence of rays of shorter wave length Ethereal waves of different length have different physiological and therapeutic properties This is quite evident when the difference is very great, as is the case with visible rays and ultra-violet rays, and ultra violet rays and X rays But it is also true when the difference in wave length is much less Thus the waves at the violet end of the spectrum are only one half the length of those at the red end, yet the former have strong chemical (actinic) action and feeble thermal action, while the reverse is true in the case of the latter In the ultra violet region the shortest measured waves are one eighth of the length of the longest The range of the ultra violet spectrum is, therefore, four times that of the visible spectrum Arcs formed between carbon electrodes, iron electrodes, silver electrodes, and others all give out ultra violet rays, but they have not all identical properties Thus, the *light emitted from* the arc between silver electrodes has a selective action on the various micro organisms of the coli group, destroying or inhibiting some, not others The ultra violet rays emitted from an arc between carbon or iron electrodes do not possess this property The essential difference between the rays lies in the length of the waves The therapeutic action of the Simpson light is due mainly to the ultra violet rays Such action that this light can produce more effectively than other ultra violet light is due to its great richness in ultra violet rays, and such action that is found to be peculiar to this light is to be attributed to the presence in it of waves of shorter length

The Simpson lamp—The lamp is quite simple The electrodes are secured in metal holders and by means of a hand screw their points can be brought into contact or separated as far as desired In one design of lamp there is a plane reflector, in another a parabolic mirror is placed behind the arc so that the reflected rays are brought to a focus A metal tray or similar device is attached to the front part of the lamp so as to catch incandescent particles thrown off from the arc when the lamp is burning The lamp is mounted on a metal stand which can be raised or lowered or otherwise adjusted so that the light can be directed where desired

A current of from 5 to 7 ampères is required When the electrodes are brought into contact and then slightly separated a brilliant arc is produced It is not a steady arc like that formed between carbon electrodes, but it splutters and occasionally it goes out This is because molten slag forms at the incandescent points and sometimes makes a connexion between them The points have then to be further separated and readjusted When the lamp is burning a white smoke forms and collects as a white sublimate on adjacent parts of the lamp and on other objects in the room

Modes of application of the light—The light may be applied in one of three ways In the "open arc" method the lamp with the plane mirror is used and the electrodes are placed 12 to 15 inches from the skin The light is applied for two minutes to begin with, afterwards the exposure may be increased to three, four, or five minutes according to the reaction observed in the skin after the first exposure The open arc method is suitable when large areas have to be treated In the "focussed arc" method the lamp with the parabolic reflector is used and the area to be treated is placed at the focus of the reflected rays This method is suitable for small lesions In the "medium focussed arc" method the rays are reflected to a blunter focus, so that areas of medium size can be treated

The vapour produced during the burning of the lamp has also been used for the treatment of affections of the respiratory passages A hood is fixed to the open arc lamp and the vapour which escapes from the narrow end of it is inhaled through the mouth or nose

Physiological effects following the exposure — The application of the Simpson light, in therapeutic doses, frequently produces an erythema It appears five or six hours, as a rule, after the exposure If the exposure is prolonged the erythema is more intense, and the skin may subsequently "peel" The erythema is not of long duration, and no bad effects have been noticed. The eyes of the patient should be covered by some opaque material (cotton wool pads are suitable), and the operator should wear blue lead glass spectacles, otherwise a painful conjunctivitis will be produced

Experience with the Simpson light —An outfit for the production of the light was installed in the electrical department at St Bartholomew's Hospital in July, 1915, and a number of cases with various types of disease have been treated There seems little doubt that the Simpson light will be useful in the treatment of some of the diseases of the throat and nose A variety of cases have been treated and satisfactory results obtained in some of them The following cases may be shortly described :—

Rodent ulcer —The patient in this case had suffered for five years The greater part of the side of the face and upper jaw had been destroyed by the disease He had received various treatments at other hospitals The cavity was filled with nodular growth and was suppurating profusely Under treatment with the Simpson light the ulceration improved rapidly After three months during which time he had 44 treatments the local condition was greatly benefited—suppuration ceased and in many parts the cavity was lined by healthy epithelium

Lupus —Four cases have been under treatment, one an old standing disease affecting the tip of the nose and vestibules This patient had been under treatment off and on for three years After 16 applications the lupus was apparently cured The second case had extensive ulceration of the floor of the mouth, the tongue gums, pharynx, larynx, and epiglottis She had been under treatment with tuberculin ionisation, &c., for two years but without improvement After 33 treatments with the Simpson light the floor of the mouth was completely healed the tongue, gums, and pharynx were better the condition of the larynx unchanged The third case in which the anterior part of the nose and septum were ulcerated, was greatly benefited by 31 treatments extending over a period of five months. The fourth case has just commenced treatment and appears to be making progress

Syphilis —Up to the present only one case has been treated at St Bartholomew's The ulceration quickly improved, but the patient was also treated with mercury and salvarsan Major E G Ffrench R.A.M C who has had considerable experience of this treatment in the primary and secondary stages of the disease stated at a meeting of the Royal Society of Medicine in November 1915 (Laryngological Section) that he was of opinion that treatment by the Simpson light if combined with other syphilitic remedies definitely shortened the period of recovery [1]

Asthma —It has been stated that cases of asthma are materially benefited by the Simpson light A patient who had suffered from severe asthma, nasal catarrh, and polypi for five years, during which time his disease had made steady progress has recently been treated with the Simpson light After 44 inhalations of the vapour during a period of four months he is now in a better state of health and is able to do full work. During the last six weeks he has been practically free from attacks There seems little doubt that in this case a definite improvement has been obtained with the treatment

Vaso-motor rhinitis —Two cases have been under treatment for a short time, and in both of them there has been a moderate degree of improvement

Nasal catarrh and sinusitis —Three cases have received prolonged treatment of from three to six months, but without any definite results

Otosclerosis —One patient is under treatment and states that she is hearing better It is doubtful, however, whether this will be a permanent result

A number of cases of disease of other parts have been treated, and good results have been obtained with some

Eczema —A patient, aged 35, suffered from intense itching and pain in the fingers of both hands that had resisted other forms of treatment for nine months The eruption was distributed on the dorsal aspect of the fingers and hands, and on both palms Sixteen applications of the Simpson light were made over a period of 20 days The open arc was used, and exposures of one minute each to back and front of hand and fingers Nothing was observed until the day after the fifth exposure, when the itching increased and the discharge became more abundant After a rest of three days the treatment was resumed daily The itching and discharge then lessened, and on the twentieth day they had disappeared together with the eruption

Lupus —The patient aged 5, had an area on the right leg, not ulcerated, measuring 2 inches by 2 inches Thirty-one exposures to the Simpson light (open arc) were given over a period of 15 weeks The length of exposure was gradually increased till, at the end of 11 weeks, its duration was seven minutes It was then gradually diminished to three minutes The patient is still under treatment. The whole area of skin with the exception of a patch ¼ inch in diameter has healed. It is slightly pigmented. The patient had previously received local medicinal treatment but without avail.

Rodent ulcer —The patient was aged 47 The ulcer was situated on the lower eyelid It had been treated by X rays and had healed, but 11 months later it reappeared When seen it measured ¾ inch by ¼ inch Six applications of the Simpson light were made during 28 days The focussed arc was used and exposures of two and a half minutes were given. The ulcer healed and was covered by soft supple skin

The Simpson light seems to stimulate the healing of wounds Cases of shrapnel wound have been tried and have benefited from the treatment When disease affects the deep parts or subcutaneous parts there is usually, though not always, no benefit Cases of rheumatoid arthritis have been treated, usually without providing relief, although some patients with the disease affecting the finger joints have said that their pain has been greatly relieved One patient with considerable swelling of both sides of the neck caused by tuberculous glands (without sinuses) has been greatly improved, there being no evident swelling on one side and a much diminished swelling on the other A case of exophthalmic goitre was treated, but without beneficial result Some inoperable malignant ulcerated growths have been exposed to the rays In some of these pain has been relieved, but, excepting the cases of the rodent ulcer mentioned earlier, without any other benefit

The method is at present in its infancy, and it is too early to form any opinion as to the value of the Simpson light in the treatment of the different diseases The first impression obtained, however, is a promising one It seems probable that the light will be of distinct value in the treatment of superficial ulcerations, especially those which are of a purulent character Investigations should be made to determine how this light compares with other arc lamps The exposure required with it is a short one which is an obvious advantage It seems possible that in some diseases cures will be obtained more quickly than with other treatments Beyond a slight reaction, which is quite definite when a long exposure has been given, no bad results have been seen

HYPERTHYROIDISM AS A CAUSE OF THE IRRITABLE HEART OF SOLDIERS

By C PERCIVAL WHITE, M B , B C CANTAB ,

AND

FRANCIS HERNAMAN JOHNSON, M D ABERD ,

CAPTAIN (TEMP) R A.M C CONSULTING RADIOLOGIST
ALDERSHOT COMMAND

THE following cases seem to us worth recording as they may explain many of the so called "irritable hearts" which are now so common in men home from the front

CASE 1 —The patient, aged 28 admitted into the Herbert Samuelson Hospital for Officers, and first seen by one of us (C P W) on April 13th, 1915, had been at the front for eight months, and had there been subjected to great strain As all his work had to be done at night he had been very short of sleep He complained of palpitation, the pulse even in bed varying between 90 and 100 per minute, though quite regular There was no cardiac murmur , the apex was in the nipple line The temperature was slightly raised , he suffered much from sleeplessness He improved to a certain extent while in hospital and left on May 6th to go home and to lie in the open air He did fairly well until the middle of August, when he became very breathless and was hardly able to walk a hundred yards He came under observation again on Sept 30th I had seen him only once since he left London, and I was much struck with the change The thyroid gland was enlarged, he had well marked Stellwag s sign, fine tremor of the hands, a pulse rate of 120 apex in nipple line, and no murmur He was breathless on the slightest exertion All the typical signs of Graves's disease were present, he came into hospital again The pulse rate after a few days' complete rest varied from 98 to 84, and the respirations were 28 to 34 per minute

After three weeks' rest in bed one of us (F H J) gave him some X ray treatment Sittings were three times weekly and it was only possible to give seven in all The patient then said that he felt so much improved that he considered himself equal to travelling north to attend to urgent business affairs It is difficult to say how much of this alleged improvement was imagined as the result of the patient's wish to escape All that can be said on the physical side is that during the last few days while he was up the pulse was no worse than when he had been confined to bed In civil practice a few cases certainly do show definite benefit from X rays in a fortnight, but a month is generally necessary for any effect to be seen

CASE 2 —The patient had been wounded at the base of the neck and the left shoulder (June 28th) after two months compaigning in Gallipoli, during which time he was under fire the whole time He was confined to bed between two and three weeks As soon as he was allowed to get up he began to be troubled with profuse sweats He slept badly and felt restless and *unsettled His legs seemed* scarcely to belong to him " and any exertion made him breathless He was first seen by one of us (F H J) early in September when he still complained of all the above symptoms though of course in somewhat less degree than when he first got up He thought, however tha there had been no improvement for a month or more He complained much of aching in the wound, which, though healed presented an angry looking scar To look beyond the natural effects of exposure shock, and continued pain to furnish an explanation of the symptoms had not been thought of Consequently treatment by high frequency vacuum electrode was prescribed for the neck and shoulder, together with the sinusoidal bath as a general tonic Under this treatment the pain lessened, but the general condition remained unimproved He *complained* of night sweats which left him limp in the morning Belladonna was prescribed for these, and it produced some improvement So matters stood at the beginning of October, when it was thought desirable to re-examine the patient carefully in the light of Case 1. There was slight exophthalmos, definite enough when looked for , also the pulse was 120 The hands showed tremors when held out The thyroid gland was definitely enlarged, and pulsation was distinctly visible The clinical picture was thus illuminated as by a flash, and the whole of the symptoms fell into their proper place It was, in fact, a typical, and—rightly looked at—obvious case of Graves s disease Exophthalmos, enlarged and pulsating gland, tremors, sweatings tachycardia, breathlessness, irritability —nothing was lacking

The patient was doing light duty, which he was very anxious not to relinquish He was unwillingly allowed to continue this for a time while X rays were being tried. He has had treatment for two months The pulse is 100 Sweating is now of very occasional occurrence The tremor has gone The thyroid gland is smaller in size, and there is very little pulsation Exophthalmos remains unchanged but it was never very *marked The patient states* that he feels himself to be making progress every week

CASE 3 —The patient, aged 40 years, had in February 1915, been sent to Egypt At that time he felt in perfect health, and carried out all his duties for a period of three months His work was of an extremely arduous nature, and he began to feel the heat very much about the beginning of May *Towards the end of that month he began to* feel unsteady on his legs and to be troubled with shortness of breath He was sent home in July and was first seen by one of us (F H J) on Oct 1st At that time there was marked exophthalmos, and fine tremor in the hands which felt clammy to the touch The pulse rate was not markedly high (84) The patient was doing a certain amount of duty, and his chief complaint was that the least extra exertion made him short of breath

X ray treatment was commenced and was given three times a week The patient announced an improvement after four weeks In two months he stated definitely that he could go upstairs without feeling "puffed" and that he felt it would not be very long before he was fit for full duty

With regard to the first of these cases, the interest of it lies in the fact that many cases of irritable heart may be explained by a condition of hyperthyroidism, a sort of pre Graves condition the rapid pulse, sleeplessness, and tremor being the only signs present We know that prolonged strain and shock are common predisposing causes of exophthalmic goitre, and these factors are, of course, present in marked degree in most instances of so called " soldier s heart '

The patient in Case 2, although showing all the typical signs of Graves s disease early in October, had been seen by several medical men since he was invalided home without the diagnosis being arrived at It is *probable that the full clinical* picture developed gradually, and that, had one been on the alert, the condition could have been recognised at an earlier date and treated accordingly

Case 3 provides a kind of link between the Graves s disease of civil practice and that presumably brought on by the rigors of active service This patient had not actually been under fire, and, of course, his trouble might have developed in any event

There was no sort of *a priori* certainty that the same excellent results obtainable by X rays in ordinary cases could be duplicated in the "military" form of the disease, but, so far as our experience has gone, this treatment appears beneficial

It is to be specially noted that the patients in Cases 2 and 3 continued to do a certain amount of duty That the third patient should be practically cured and the second very much improved in two months under such circumstances may, we think, be considered encouraging, but it is probable that rest is even more desirable in military cases than in those occurring in private practice

The treatment of irritable heart in soldiers has hitherto been decidedly of an "expectant nature, and it would at least seem reasonable that in all cases where there is a suspicion of hyperthyroidism X rays should be tried, other suitable measures, of course, not being neglected We are of opinion that investigation and treatment on the lines above suggested will alter for the better the prognosis in the type of case known at present as "irritable heart of soldiers"

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

CASE OF SHRAPNEL INJURY TO RIGHT PARIETAL CORTEX,

SHOWING PARESIS OF LEFT LOWER EXTREMITY, TOGETHER WITH CORTICAL SENSORY LOSS AND THALAMIC OVER RESPONSE

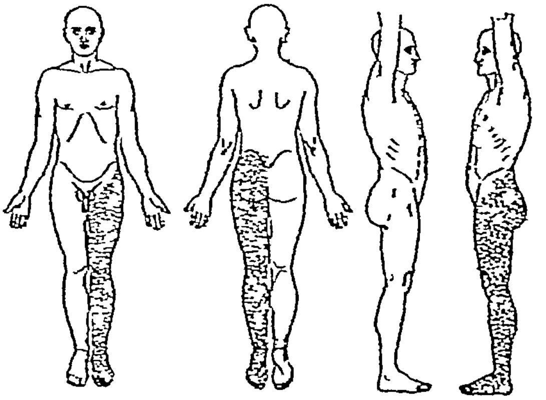
BY H. M ANDERSON, M.B, CH.B EDIN,
CAPTAIN R.A.M.C

AND

H. L. C NOËL, M.R C S, L.R C.P LOND,
LIEUTENANT R.A.M.C

WE consider that the following case is of sufficient interest to publish as it shows a comparatively rare combination. There are two definite sensory changes to be distinguished First, there is the sensory loss due to functional disturbance probably of a circulatory nature arising from local pressure on the post Rolandic cortex. This accounts for the loss of posture, the inability to distinguish compass points, the persistence of deep touch, and possibly for the blunting of cotton wool touch over hairless areas On the other hand, we have to consider the over reaction to stimuli of an affective nature such as heavy prick and stroking This is of thalamic origin, and is explained by the throwing out of action of the cortex which normally exerts an inhibitory influence over the thalamus The reason why thalamic over response is seldom a well marked feature of the cortical sensory lesions seen in this war it is difficult to say, in this case the amount of brain damage was small and the consequent shock slight—a possible explanation. The area determined by the line of change is interesting in that it approximates more closely to a "mind" or hysterical loss than any other area due to an organic lesion On the motor side the involuntary movements are undoubtedly of reflex origin, and probably represent the efferent expression of the thalamic level. In support of this hypothesis we have their relation to affective stimuli, especially when arising from the mucous membrane of the glans penis As such they are comparable to the well known involuntary movements which accompany certain emotional states, such as shyness

Private —— was admitted to a general hospital on July 31st, 1915 suffering from a wound of the head received on the 26th He gave a history that after being hit by shrapnel he was unconscious for about 10 minutes He was carried to a dressing station, being unable to walk on account of weakness and numbness of the left leg Since then he had complained of numbness of the left leg and headache On admission there was a small perforating wound at 8½/14¼" 1¼" to the right of the middle line There was no œdema of the scalp or tenderness of underlying bone. The X ray showed two pieces of metal in the outer table of the skull in the posterior parietal region with a depressed fracture below Examination of the nervous system revealed no abnormal changes in the eye movements, the pupils, or the visual fields, the face and tongue were straight there was no weakness or ataxia of either upper extremity The right lower extremity reacted normally to all tests In the left lower extremity all movements were possible but there was definite weakness of the toes, and the extensor longus digitorum was observed to act more strongly when the patient dorsi flexed the ankle than when he attempted to extend the toes On the left side the knee jerk was exaggerated, ankle clonus was just obtained, the plantar reflex was extensor and the abdominal was abolished.



Over the dotted area shown in the chart there was marked over-reaction to pin-prick, and passing from above downwards the line of change was quite definite, over the whole limb moderate prick was less "sharp" and heavy prick more painful than on the right side Over the hairless areas of the leg and foot there was blunting to cotton wool touch, cotton-wool over hairs was well appreciated, but felt different from the right side. Temperature sense, vibration on bone and on pinched up skin were normal There was considerable persistence of deep touch from the sole and compass points could not be distinguished at 6 cm along the inner border of the foot. The position of the hip and knee was impaired and there was complete loss of position of toes Localisation was accurate Spontaneous movements of an irregular and jerky character affecting the whole limb occurred from time to time or could be elicited by any painful stimulus applied to the leg or by gently stroking the limb with cotton-wool, these movements were, however, most marked on tickling the sole of the foot or on gently pricking the left side of the glans penis the latter causing great discomfort to the patient Stimulation of the sole gave a feeling like an electric current passing through the leg

On August 2nd an operation was performed. A penetrating wound of the outer table was found with depression of the inner table, a blood clot occupied the interval between the two tables The depressed portion of bone measured ⅞ inch by ⅜ inch, and was driven down on to the dura to the extent of about a quarter of an inch. The dura was intact. After operation the sensory changes began to clear up rapidly On the patient's discharge to England on August 13th he reacted normally to gross tests.

TRAUMATIC DISLOCATION OF THE HIP JOINT IN A CHILD

By HARRY PLATT, M S LOND, F R C S ENG,
SURGEON AND SURGEON IN CHARGE, ORTHOPÆDIC DEPARTMENT ANCOATS HOSPITAL, MANCHESTER

AND

H M VON MENGERSHAUSEN, M.B, CH B VICT,
SENIOR HOUSE SURGEON ANCOATS HOSPITAL.

IT is well known that the occurrence of traumatic dislocation of the hip joint in children is a very rare event We recently had an opportunity of seeing this condition in a child

The patient was a boy aged 6 years When running down a hill he slipped, fell forward on to his face, and rolled over and over several times He felt something "give" in his left hip The mother brought him to the Ancoats Hospital within an hour of the accident It was impossible to obtain an accurate description of the exact violence and the position of the limb at the time The left lower limb was held in a position of flexion, adduction and inversion at the hip The limb was obviously shortened and the trochanter unduly prominent On palpation the trochanter was found to be elevated above Nélaton's line and the head of the femur could be felt on the dorsum ilii There were no signs of bruising and no crepitus was elicited Under anæsthesia the dislocation was reduced with ease by flexing the limb on the abdomen and then abducting as in the Ridlon method of reducing a congenital dislocation A long Liston splint was then applied An X ray plate taken after reduction showed no local anatomical abnormality which might have predisposed to dislocation, the femoral heads and acetabula being perfectly symmetrical At the end of three weeks the splint was discarded and the boy was allowed to kick his leg about in bed at will He rapidly gained mobility in the affected joint When seen two months after the accident he was walking without perceptible limp The hip showed full range of motion, and there was no pain or instability

Boehnke[1] has collected from the literature 29 cases of traumatic dislocation of the hip joint in children, and has described a case of his own It is probable, however, that this condition is hardly as rare as these figures would suggest, for it is only long standing cases and those which give trouble in reduction which are likely to be recorded The case reported by Boehnke is typical of the majority of the published cases—viz, a child aged 6 years seen 11 weeks after the injury, and in which arthrotomy was required to effect reduction after failure of manipulations In the above series of cases 23 were posterior and seven anterior dislocations, proportions which correspond to those usually given for hip dislocations in general It is interesting to note in these cases the relationship of the duration of the displacement to the feasibility of performing bloodless reduction In most instances an open operation was necessary after three weeks, though in two cases (quoted by Endlich) reduction was obtained by manipulations six and a half weeks and three months after the injury respectively On the other hand, bloodless reposition failed in two cases which had existed 14 days only (Helferich, Hirsch) As the small number of dislocations recorded were under the care of almost as many different surgeons, there would be no uniform standard of skill The chances of success in either method of reduction in long standing dislocations will be dependent on the training and experience of the operator in dealing with congenital cases

Medical Societies

ROYAL SOCIETY OF MEDICINE

SECTION OF PSYCHIATRY

Clinical Evening

A CLINICAL meeting of this section was held on Dec. 14th, 1915, at Bethlem Royal Hospital, Dr F W MOTT, the President, being in the chair

Dr J P PHILLIPS demonstrated a female married patient aged 54, who was admitted four months ago after a mental illness of six weeks, supposed to have been due to onset of the menopause Her husband stated that she began, after hard social work, to lose power of concentration, she was unable to control the movements of her hands and believed that people were against her On admission her physical condition was very poor, she was confused, could not converse, and was very restless and dirty in her habits Her reflexes were normal, with the exception of exaggerated knee jerks A fortnight after admission she was found to be comatose, having apparently had a seizure, and shortly afterwards had another, epileptiform in character, the temperature just afterwards rose to 101 4° F Treatment was followed by marked improvement, and she had lucid intervals Before lumbar puncture was carried out she was very restless and confused in her ideas, her speech was slurred, she had tremors of hands and lips, hallucinations of hearing, pupils reacted sluggishly to light, and her movements were somewhat incoördinated On these symptoms general paralysis was suspected Since lumbar puncture was done there was much improvement, and the idea of general paralysis of the insane was negatived There was an absence of lymphocytes, and Wassermann and the biochemical tests were negative —Sir GEORGE SAVAGE said he had seen cases of chronic mental disorder develop fits on occasion, of an epileptiform character, and he raised the question as to whether that meant a further degeneration of the brain, and a grave prognosis —The PRESIDENT noted that the thyroid was enlarged, the skin was dry, and the hair scanty In some cases, however, the enlargement turned out to be a pseudo-hypertrophy He had described some cases in which the mental symptoms were due to hypothyroidism, but the improvement after lumbar puncture excluded the present case from that group If there should be any relapse, he thought thyroid treatment might be tried —Dr J N SERGEANT, who saw the case earlier, said the patient was much worried about her supposed unworthiness and doubted whether she had done her best for her children and home.

Dr PHILLIPS also showed a single woman, aged 23 the subject of hysteria Two years ago she had a nervous breakdown, due, it was supposed to a love affair From this she partially recovered For five months she suffered from anæmia and indigestion, and when discharged from the hospital in the provinces where she was a voluntary boarder, she was unable or refused to walk. She complained of headache could not occupy herself, threatened suicide and was impulsive Last June she was certified, and at that date she suffered from insomnia, noises in the head and continuous dull headache She was also very thin and weak and emotional, and suffered from tachycardia She also had hesitating speech and an unsteady gait She was now much better, but he regarded the case as on the borderline of insanity —Dr ERNEST JONES did not see any evidence of any variety of psychosis in this case It seemed to present the clinical picture of an anxiety hysteria the symptoms and the whole course of the case seemed to support that view

The next case shown by Dr PHILLIPS was that of a man aged 57 whose illness was attributed to excessive work and worry He had melancholia 15 years ago, when he attempted suicide by drowning Two months ago he walked out of a window on the second floor of his house When admitted last month he complained of depression with pains in his head and back, there was marked tremor of the hands and lips, slowness of speech and asthenia. Glycosuria had been present, in degrees varying between 0 5 and 2 per cent. There had been no improvement, and he now suffered from hallucinations of hearing, and his pupils exhibited a sluggish reaction to light Lumbar puncture had been done, and the examination was negative —Sir GEORGE SAVAGE reminded the section of the observation of Dr Maudsley that there was an alternation between glycosuria and melancholia, which he (Sir George Savage) had amply confirmed If diabetics had mental disorder, they usually lost the sugar in the urine. In one particular case at Bethlem no sugar could be found in the urine as long as the patient was excited, but it reappeared in the intervals —The PRESIDENT pointed out that the determining factor in deciding whether it was a toxic condition was the presence of aceto-acetic acid or acetone in the urine. (Dr Phillips had said those substances were not present in this case.) With regard to the Wassermann reaction, in 97 per cent of cases of general paralysis the cerebro-spinal fluid gave a positive result, and in the serum in 98 per cent Clinically he did not regard either this or the first case as general paralysis He suggested that attendants should be instructed to describe exactly the kind of fit patients had when a medical man was not near, it would prove of great service

Dr SERGEANT exhibited a male patient, aged 41, who was certified in consequence of a condition of acute mania, following excessive drinking and the use of drugs He first showed abnormal suspicion, melancholia, and refusal of food He now had ideas of persecution based on hallucinations of smell and taste Lucid intervals, however, occurred during which memory, perception, and orientation seemed unimpaired. While the compound fracture which he sustained by jumping off the top of an omnibus was in a bad condition the mental condition seemed clear, but since the healing of the leg condition he had been imitative and worse mentally, as if he were trying to live up to the reputation he had entered upon. Once he kept silent for 42 days, but at times he was strongly imitative and quick witted.—Dr PHILLIPS thought the various phases the case had passed through justified the opinion that it was maniacal depressive insanity —Dr BERNARD HART inclined to the diagnosis of dementia præcox, for the patient's history as a youth and the fact that he had never had any occupation, favoured the idea that the abnormal mentality dated back a considerable time.—Dr T SEYMOUR TUKE agreed with Dr Hart, and spoke of a similar case in his own experience. His prognosis was not hopeful.—Dr HART in further comment, said it was a well known fact that in many cases the dementia was much less than it appeared He had carried out intelligence tests in a considerable series of cases carefully graded, and the general opinion of medical observers placed the cases much lower in the scale of intelligence than the tests showed they deserved. The dementia seemed to be pronounced because the patients were shut off from their surroundings Sometimes a case of dementia præcox would, after a number of years wake up and show surprising intelligence a state of things which did not occur in the organic dementias

Dr SERGEANT also showed a female, aged 40, whose mental illness dated from pneumonia and pleurisy following influenza 21 months ago She was very restless slept badly, complained of headache, was sensitive, irritable, and expressed a wish for self-destruction She had occasional auditory hallucinations and though formerly an ideal wife, she was now quite apathetic about her family

---

LONDON DERMATOLOGICAL SOCIETY —A meeting of this society was held at St John's Hospital for Diseases of the Skin on Dec. 21st 1915 Dr J L. Bunch the President being in the chair —The President showed a case of Bichromate Dermatitis in a man, aged 81, who had peculiar purpuric lesions present on the left hand —Dr W Knowsley Sibley showed a case of Actinomycosis in a man aged 37 —Mr C R. Kempster showed a man who had received a scratch on the left ear with a piece of barbed wire three years ago Ten weeks ago he had a large fungating cauliflower growth present in this region, a section was examined and was found to be an epithelioma. The patient had been treated with X ray 10 applications full pastille doses and the lesion had practically disappeared.—Dr R Prosser White (Wigan) read a paper entitled "Some New Forms of Occupational Dermatitis"

Reviews and Notices of Books.

Oral Surgery A Treatise on the Diseases, Injuries, and Malformations of the Mouth and Associated Parts

By TRUMAN W BROPHY, M D, D D S, LL D, Sc D, F A C S, President and Professor of Oral Surgery, Chicago College of Dental Surgery With Special Chapters by MATTHEW H CRYER, M.D, G HUDSON MAKUEN, M D, WILLIAM J YOUNGER, M D, F W BELKNAP, M D, CALVIN S CASE, M D, D D S With 909 illustrations, including 39 plates in colour London Henry Kimpton 1916 In two volumes Pp 1090 Price 2 guineas

To appreciate this volume it must be recognised that though it will prove of interest and value to most surgeons, yet it is primarily intended for the dental student, many of whom do not study medicine Accordingly it is prefaced by a general description of the principles of surgery We find here accounts of surgical bacteriology and infections, there are chapters on syphilis and tuberculosis, on wounds, antisepsis, hæmorrhage and anæsthesia, fractures and dislocations, and diseases of bones and tumours are the subjects of some of the chapters, and in our opinion this introductory material is very well put together Then we come to that portion of the work which is more particularly concerned with the mouth. We have chapters on the infections of oral origin, the diseases of the tongue and of the tonsils, dislocation of the jaw and ankylosis of the temporo maxillary joint, the extraction and transplantation of teeth, cysts and tumours of the jaws, trigeminal neuralgia and diseases of the salivary glands The most important chapters, however, are those which deal with hare lip and cleft palate, and these are indeed valuable, for while much of the book could have been written from the experiences of a surgeon with general hospital practice these chapters deal with a subject which the author has made specially his own. He has devised new methods which in his hands at least have given almost perfect results, and we rejoice to have so complete a presentment of the author's ideas Many surgeons associate the name of Brophy *only* with the special operation which is called by his name, and which consists in the forcible pressing together of the two maxillæ in very young infants, but, as a matter of fact, he has made important additions also to the operations employed in older children and in adults, and his results more than justify the procedures he adopts

Professor Brophy lays down the principle that the earlier the operation for cleft palate is performed the better, provided that the health of the child is satisfactory If the child is under 5 months of age he holds that the approximation method is the best treatment, and that the ideal time for the operation is the second week of life. If, however, the child is older than this it will be impossible to adopt the method If a hare lip is present as well as a cleft of the palate we are told *that* the palate should be closed before any operation is performed on the lip, as the cleft in the lip will give much needed room for the operation on the palate He does not consider it necessary in the great majority of cases to make any lateral incisions in the palate for the relief of tension, but he employs leaden plates fixed with wire sutures to overcome the strain The subject is important, and we do not attempt a discussion of all the aspects of the questions involved, but here we have the facts and arguments which support Professor Brophy's opinions, and we refer to the book itself every reader who desires to investigate the subject fully

The book is freely illustrated, and most of the illustrations are very happy, but in a few the photographs of the interior of the mouth show very little It would surely be worth while to have some of these photographs redrawn

Instinct and Intelligence

By N C MACNAMARA, F R.C S Eng London Henry Frowde and Hodder and Stoughton 1915 Pp vi -216 Price 6s net

THIS volume is a plea for a modification of the present system of education Mr Macnamara states his thesis in the following words "The animal side of man's nature results from a specific arrangement of elements entering into the formation of his central nervous system which he has inherited from his progenitors, and cannot, therefore, get rid of or permanently alter" These abiding elements he believes to be chiefly resident in the great basal ganglia of the brain, which are so remote from experimental investigation in the higher animals that their functions are but little understood, though they are obviously of great importance Such a doctrine of inheritance of nervous traits would be barren or fatalistic if it were accepted baldly Mr Macnamara maintains, however, that the action of the basal ganglia can be modified by educating and influencing them through the sensory organs or by energy derived from the higher association areas of the neopallium, that mass of nerve tissue which has been added in the course of ancestral development to the modest nervous outfit with which animal protoplasm started on its ambitious career In the majority of healthy children these modifying influences can be attained by the appropriate exercise of the eyes, ears, and other sensory organs, for by their means instinctive qualities may be directed into useful and improved channels It is necessary that the body should be healthy if the best results are to be attained, and Mr Macnamara lays especial stress, therefore, on the need for a healthy environment at home as well as in school for the poorer classes, whilst in our large public schools it would be better if the master endeavoured to discover the disposition of each boy in the light of his parental attributes rather than inquire about the infantile ailments from which he has suffered

The book is valuable to all who are concerned with educational matters, as it gives abundant food for thought It is interesting because the author gives an excellent account of the nervous system as it exists in the various animal sub kingdoms

English Public Health Administration

By B G BANNINGTON, Inspector of Nuisances, County Borough of West Ham, Certificate Royal Sanitary Institute, Gilchrist Medallist Political Science, Society of Arts Medallist Economics, late Scholar, London School of Economics London P S King and Son, Limited 1915 Pp 338 Price 7s 6d net

Mr Bannington's work forms one of the series of studies in economics and political science edited by the Hon W Pember Reeves, Ph D, and in an appreciative introduction Mr Graham Wallas, professor of political science in the London University, indicates its object and the scope of the instruction that it will afford We agree with him that the student has hitherto had to content himself with popular handbooks or with chapters dealing with the public health in works on local government, and that the official has found in Lumley's "Public Health Acts" an admirable text book for reference in the discharge of strictly technical duties, but that neither has had compiled for his benefit a practical treatise which he can read and remember Mr Wallas excepts as a general treatise "English Sanitary Institutions," which he describes as obsolete, written by the present Home Secretary in the earlier days of his busy legal career, and, with this exception, we have no doubt that Mr Bannington's book will for the present stand alone, and that it will be welcomed as the production of a thoroughly practical and experienced man with considerable powers of lucid expression and orderly arrangement

It has hitherto been difficult to recommend to medical practitioners and others desirous of obtaining a more than superficial knowledge of public health legislation and of its administration anything in the nature of a readable book and not a precis of Acts of Parliament and Orders, and the need for such a work may well have been responsible for the indifference of many members of local authorities towards an important branch of their duties For the purposes indicated we believe Mr Bannington's book will be found extremely useful And as he gives constant reference to authorities in his text and footnotes, it will be easy for anyone who desires to examine any particular point in detail to follow the matter up as far as he pleases He will, moreover, find a useful bibliography of the subject on the pages preceding the index Medical officers of health will naturally see in such a work much with which they are familiar, as connected with the performance of functions which to them are a matter of routine They should however, also be able to trace useful suggestions as to the possibilities of their office in such chapters as that on registers, records, and reports, while there are many matters for their consideration in the observations upon official status and security of tenure While maintaining the general desirability of this security of tenure for all health officers, Mr Bannington does not conceal his opinion that the local authority will usually be master of the situation whenever it sets its corporate mind to the task of getting rid of any officer He suggests that the process of making the life of the object of its dislike burdensome and unpleasant will always be possible to a public body, and that the refusal of the Local Government Board to sanction a dismissal may be of little practical value when the Board and the local authority come into conflict

The history of public health legislation may be traced back through the Middle Ages to the Pentateuch by the aid of the author's introductory chapters, though in its modern and more effective development it is a very modern history As such this history may be recommended to the study of our present legislators, who should be encouraged in continuing the work which they have begun by the results achieved They will find in the author's concluding chapter a plea for simplification and codification, for which any legal library supplies an unanswerable argument in the bulky volumes of Lumley's "Public Health Acts already referred to And they will also be reminded that in the present and coming crisis in the nation's affairs every step taken to promote efficiency, combined with rigid economy, and to prevent overlapping and extravagance on the part of public bodies charged with the care of the public health is of supreme and increasing importance

---

With the Turkish Army in the Crimea and Asia Minor a Personal Narrative

By THOMAS BUZZARD, M D Lond, &c London John Murray Price 10s 6d net.

IN the sound, smooth prose which he has at command Dr Buzzard recalls his experiences as a member of the staff of surgeons who, early in 1855, left England for the Crimea to supplement the surgical aid which up to then had been found insufficient by the British officers under Omar Pasha. A young man in the early "twenties," a Member of the Royal College of Surgeons of England fresh from well utilised opportunities in hospital practice, he embraced his mission with the alacrity of the professional enthusiast who enters on a field of practice prolific in surprises and new developments The seat of war, moreover, had the special attraction of classical association for the young surgeon who had not forgotten his Æschylus or his Xenophon, and who possessed not only the literary but the artistic instinct which found expression, as occasion offered, in many a graphic descriptive letter and many a water colour sketch

The journey out in those days was neither so comfortable nor so expeditious as it has since become, and the vicissitudes of travel by land and sea are described by Dr Buzzard with something of the frolic welcome congenial to robust health, high spirits, a sense of humour, and a happy exemption from the *mal de mer* On reaching his destination he found that (all too characteristic of the home authorities) the staff had not been secured the recognition due to it at the Turkish headquarters and that consequently its services were denied their proper scope The result was a long period of idleness, almost absolute, at Eupatoria which, to one of fewer non professional resources than Dr Buzzard must have been painfully irksome, but which he effectively relieved by study, topographical, climatic, and other, as well as by watching, wherever practicable, the operations at the front Incidentally, too, his knowledge and skill were in requisition, not least in the epidemic disease then more fatal to an army *in the field* than the actual fighting Cholera, for instance, was widely diffused, and would have numbered many a victim but for Dr Buzzard s advice to avoid the water, for his friend, John Snow, had the year before during the cholera explosion in Soho demonstrated drinking water to be the vehicle of the malady Relief to the wounded was also a frequent practice of his, on occasion of his riding over the war zone—particularly during the battle of the Tchernaya, the episode of which came under his eye Some of these scenes he describes with a pictorial impressiveness which has all the effect of a vivid sidelight on the official report—a contribution to the intelligent appreciation of the scene which is equally illuminating in his account of the siege of Sebastopol. On the fall of that stronghold Dr Buzzard and his colleagues on the staff were told off under the Deputy Inspector, Dr Farquhar, to Trebizond and Sinope, there to establish and equip on a satisfactory footing the hospitals, which in Turkish hands were lamentably defective This task, in which he took a conspicuous part, proved a blessing to Omar Pasha s command and earned the cordially expressed gratitude of that able and humane general

Further than this we need not follow Dr Buzzard's narrative, which will be found an eminently interesting and instructive commentary on many phases of the war not included in the monumental work of Kinglake The sketches which illustrate the letterpress are those of an accomplished artist who has found his pencil a pleasant distraction throughout a long professional career, academic, clinical, and consultant. His pen, too, has proved to him not less of a recreation, as may be inferred from the freedom and the skill with which he wields it Witness the chapter entitled "A Wild Night," in which he describes a robbery, partially successful, perpetrated by two marauders in the tent which he shared with a colleague The description is not unworthy of Dickens, of whom Dr Buzzard is a manifest, not to say grateful, admirer

---

Morphology and Anthropology A Handbook for Students

By W L H DUCKWORTH, M A., M D Cantab Cambridge University Press Second edition. Vol I 1915 Pp 304 Price 10s 6d net

As a guide to physical anthropology this handbook is greatly to be commended to those students who have already a fair knowledge of comparative anatomy, at any rate of vertebrated animals But after this much is taken for granted, the student will learn the necessary and preliminary facts for the further consideration of anthropology pure and simple

The volume is really an account of the general anatomy of the order Primates, with such reference to mammals lying lower in the scale as is necessary to the right understanding of those general facts Abundant and detailed tables of anatomical characters help usefully to fix in the mind in a crystallised condition the essential points of structure which it is incumbent upon the student to have later at his fingers' ends, if he would consider the structure of man and his place in the zoological system All of these anatomical facts are set forth in very clear language and to a large extent they are illustrated for the student by plain figures in the text It is a feature of this work that these illustrations are to a considerable degree quite new and have the further advantage that they are direct copies of bones or preparations in the Cambridge Museum, *and* can thus be handily compared with their originals To the order Primates Dr Duckworth refers the lemurs, following some though by no means all, systematists, again, in accordance with the views of some he would place the little *tarsius* of the East (of which a figure is given) in a suborder by itself, the two remaining suborders being the rest of the "lemurs"—i.e., Lemuroidea, and the apes and man lumped together as Anthropoidea. The inclusion of the lemurs and *tarsius* with the Primates is insisted upon almost entirely on account of the *brain* structure so amply elucidated of late years by Dr Elliot Smith, but this inclusion is hardly in accord with the general anatomy of the animals concerned In view of difference of opinion it may be freely conceded that Dr Duckworth is perhaps safer in including than in refusing to include the "half apes" among the true apes and man Having taken this step, the author does not ignore the diversity of structure shown among the lemurs, and gives all of the principal facts in their anatomy where they differ from the higher "Primates"

Dr Duckworth refers to some of the literature of his subject, but does not overload his pages with references Possibly he goes a little way towards the other extreme It gives one rather a shock not to find the name of Owen mentioned in his index of authors quoted in this really valuable handbook

---

Old Age Pensions Their Actual Working and Ascertained Results in the United Kingdom

By H. J HOARE, B Sc, LL B, Clerk of the Local Pension Subcommittee for Camberwell and Lewisham London P S King and Son, Limited. 1915 Pp 196 Price 3s 6d net

THIS little book has been written to serve as a "practical and human account of the actual working and ascertained results of the Old Age Pensions Acts, 1908 and 1911," and not as a legal text book for the guidance of lawyers It is well calculated to fulfil its object, and should prove of use for the instruction of the ordinary citizen who takes an interest in the minor workings of our Governmental Providence, as well as of those engaged in the administration of the Acts At the same time the suggestion may be made that a book which, though not written for the use of lawyers, is devoted to explaining or criticising Acts of Parliament loses by not having those Acts incorporated in it In this instance the Acts and the rules for administering them would not have taken up much space in an appendix, and the addition of an index or of a full table of contents would have been no disadvantage

Mr Hoare has some suggestions to make for the improved working of the Acts which he puts forward in a concluding chapter The changes which his experience causes him to suggest are not of a revolutionary description, but we note that he considers that a pensioner entering a Poor law institution for medical or surgical assistance should have his pension discontinued after four weeks He appears to desire that the forfeiture thus taking place should be permanent and not merely co extensive with residence in the Poor law institution, the hardship of which would be that even after many weeks the pensioner might recover and be as well able to live outside as he was before We should like to see the reasons for such a proposal more elaborately stated before expressing any assent to it

Some observations and statistics with regard to the extent of the relief afforded to the rates by old age pensions will be found in a chapter entitled 'Statistics of Working,' and a good many subjects, such as whether the failure to maintain a decent standard of personal cleanliness should disqualify for a pension, and questions other than that mentioned above arising out of the acceptance of medical Poor law relief, are treated briefly and clearly In short, a bird's eye view of the Acts in the working is presented, unimpeded by any excess of detail, and we commend the book to those of our readers whose work brings them in contact with the questions dealt with

LIBRARY TABLE.

Handbook of Physiology By W D HALLIBURTON, M D Lond, Professor of Physiology, King's College, London Twelfth edition With nearly 600 illustrations in the text, many in colours, and 3 coloured plates London John Murray 1915 Pp 924 Price 15s net—The eleventh edition of this handbook was reviewed in THE LANCET of Dec 13th, 1913. The alterations are of a very minor character The number of illustrations in the two editions are exactly the same—577—and we found no additions or removals The number of pages (924) exceeds by one the number in the last edition Here and there we found a slight alteration or addition in the text, e g, under fever, but practically page for page both the text and the pagination are identical in the two editions

Lessons in Elementary Physiology By THOMAS H HUXLEY, LL D, F R S Enlarged and revised edition. London Macmillan and Co 1915 Pp 604 Price 4s 6d—The original edition of this perennial and concise elementary physiology was published in 1866 It was revised by Michael Foster, and although the present editor does not mention it, Foster, in the preface to the edition of 1899 states that "my friend, Dr Lea, and I have undertaken a task of great difficulty" How admirably Foster and Sheridan Lea succeeded, the many times that successive editions were reprinted attest The present edition is the sixth Joseph Barcroft, of Cambridge, has undertaken the restoration of the work from the dilapidations of time Any portion of the fabric in which there was not an actual flaw the editor has faithfully left untouched Any repairs are substantial and thorough The edition of 1899 runs to 611 pages and the present one to 604 The number of illustrations—185—in the present edition is less by two than in that of 1899 The work has retained all its characteristic features and has been brought up to date by judicious emendations

Aids to Physiology By JOHN TAIT, M D Edin, D Sc., Lecturer in Experimental Physiology, Edinburgh University, and R A KRAUSE, M D Edin, D Sc., Lecturer in Hygiene, College of Hygiene and Physical Education, Dunfermline London Baillière, Tindall, and Cox 1915 Pp viii-242 Price 3s 6d net—It is stated that this little book is written as an aid to the student who is presenting himself for examination and who has already attended lectures and practical courses in experimental and chemical physiology and in histology It cannot in any sense replace the physiological text-book, lectures, or practical work It is founded on the "Aids" written long ago by Mr Peyton T B Beale Candidates preparing for the Examining Boards who do not exact a high standard of physiological knowledge may find it useful So far as it goes, the matter is excellent and concisely put

Elementary Chemical Microscopy By EMILE MONNIN CHAMOT, B S, Ph D, Professor of Sanitary Chemistry and Toxicology, Cornell University First edition London Chapman and Hall, Limited New York John Wiley and Sons, Inc. 1915 Pp 410 Price 12s 6d net—This is a suggestive book, illustrating, to quote the author's words, 'the benefits to be gained through the intelligent application of chemical microscopic methods in the industries and in research" Of the American chemist the author thinks that while he is usually ready to accept with alacrity all time labour, and money saving devices, he has been strangely backward in recognising the expeditious value of the microscope in analytical researches Professor Charnot holds that the microscope is a more important adjunct to the laboratory than the spectrometer, polarimeter, or refractometer, and ranks it in importance next to the analytical balance itself He certainly makes out a good case in favour of giving increased attention to micro chemical methods The earliest comprehensive work dealing with micro chemical methods was, says the author, from the pen of an American—Theodore G Wormley—whose classic, "The Microchemistry of Poisons," appeared in 1867 We appreciate this reference to a very valuable book, but the microscope was employed in analytical methods some years before this During the years 1851, 1852, 1853, and 1854, the "Reports of THE LANCET Analytical Commission" were published in this journal, and the disclosures then made as to the enormous amount of adulteration of food and drugs going on were effected by the aid chiefly of the microscope Thus the microscope really proved to be the foundation of our present Food and Drugs Acts, for legislation soon followed the reports of this Commission. But Professor Charnot has developed a very fascinating branch of analytical methods, for to watch a chemical reaction under the microscope is a most attractive occupation. It is even more attractive, we think, when the test-tube in which the reaction is taking place is put in the field of the optical lantern and the changes are projected on the screen We strongly recommend this book to the attention of all those engaged in analytical operations It is quite remarkable what a number of well known reactions or tests, qualitative as well as quantitative, can, as the author clearly demonstrates, be "intensified," so to speak, or made more sensitive by the aid of the microscope

A Text book of Medical Chemistry and Toxicology By JAMES W HOLLAND, A.M, M D, Sc.D Fully illustrated Fourth edition, thoroughly revised London and Philadelphia W B Saunders Company 1915 Pp 678 Price 15*s* net—This book is evidently appreciated as it has not only reached a fourth edition, but some of the earlier editions were reprinted In our references to the previous editions we have always expressed a good opinion of this work. The plan of treatment is admirable, the subject-matter has been kept in touch with modern developments, and the ground covered meets the requirements of the medical student conveniently The present edition contains extensions on such subjects as uranium and vanadium, radium and thorium, the newer organic compounds of arsenic, the protective enzymes, hormones, while there is an entire chapter devoted to the clinical and chemical examination of fæces The coloured illustrations of certain tests are remarkably close imitations of the real thing

The Examination of Hydrocarbon Oils and of Saponifiable Fats and Waxes By Professor Dr D HOLDE Authorised translation from the fourth German edition by EDWARD MUELLER, Ph.D First English edition London Chapman and Hall, Limited, New York John Wiley and Sons 1915 Pp 483 Price 21s net.—This highly technical work calls for little comment in a medical journal, although those sections dealing with the refined paraffins now used in medicine, and the chapters on soaps and glycerine possess some medical interest The book is a valuable contribution on the subject of the examination of oils, in view of the growing importance to the world of its oil supplies We are interested in the following observations on the physiological properties of petroleum and petroleum products "Several of the high boiling petroleum products are used with success in medicine (dermatology), notably vaseline and 'paraffinum liquidum' and 'naphthalan' as the basis for salves The ill effects of other products have been demonstrated Probably the more harmful action of the higher boiling fractions, such as crude paraffin, is due to the insufficient treatment of the crude materials for the removal of oxygen and sulphur derivatives, on the other hand, the highly purified 'paraffinum liquidum' can be used." The book abounds with methods of analysis useful in the evaluation of oils, fats, and waxes

The Illustrated Medical Dictionary By W A NEWMAN DORLAND, A.M, M D Eighth edition, revised and enlarged London and Philadelphia W B Saunders Company 1915 Pp 1137 Price 19s net—The two years elapsed since the appearance of the seventh edition of this dictionary have necessitated the addition of 30 new pages, an increase of nine pages under the heading "Test," and a series of entirely new plates The title page makes the claim to be "a new and complete dictionary of the terms used in medicine, surgery, dentistry, pharmacy, chemistry, nursing, veterinary science, biology, medical biography, &c.," and for medicine and surgery, at least, we believe the claim to be well founded. The book is one which we often use for reference

---

MISCELLANEOUS VOLUMES

WE have received a number of little books dealing with ambulance work. One of these, *First Aid to the Injured and Sick an Advanced Ambulance Book*, by Major F J WARWICK, R A.M C (T) and Major A C TUNSTALL, R A.M C (T) (Bristol John Wright and Sons, Ltd. 1915 Pp 246 Price 1*s* net) is already in its ninth edition and 120th thousand. A fresh feature in the book is the incorporation of the new stretcher drill from R A.M.C Training, 1911 It will continue to enjoy its well earned popularity——A supplement to this manual has appeared in the form of *Questions on First Aid to the Injured and Sick* by the same authors (Same publishers. Pp 38. *Price 6d* net), which it is hoped will enable pupils, especially *those* who have not the advantage of attending classes, to make *their* knowledge of the subject more thorough and complete The page of the handbook on which the answer is to be found is given at the end of each question.——*Martin's Questions and Answers upon Ambulance Work* (London Baillière, Tindall, and Cox. 1915 Pp 125 Price 1*s* net) has been revised and brought up to date by Mr LEONARD S BARNES in the light of his wide experience as official lecturer and examiner to the St John Ambulance Association. The book is in small pocket form and has reached its eighteenth edition and its seventy-second thousand and evidently can serve as a reminder to what has been learned at lectures and demonstrations. For more than this its lack of illustrations would make it unsuitable.——A new publication on similar lines is *Training in First Aid and Nursing by Question and Answer* (London The Scientific Press, Ltd Pp 133 Price 1s 6d net), arranged by Captain S T BEGGS, R.A.M C (R), whose experience as a lecturer for the St. John Ambulance Association has enabled him to write with authority, and as an old demonstrator of physiology to choose an attractive series of diagrams which add greatly to the value of the book. Part II is devoted to training in nursing, and here too the illustrations are well chosen and most helpful. The book has a limp cover suitable for the pocket, is most attractively printed and arranged, and has a good index. It will make a serious competitor to the older manuals ——Learning is not the only requirement for a prophet of health and Professor H R KENWOOD in his little brochure, *Health in the Camp a Talk to Soldiers* (London H K Lewis and Co , Ltd 1915 Pp 58 Price 3*d* net , 100 copies 21*s* net), has known how to infuse his teaching with a convincing earnestness which makes it doubly attractive He has endeavoured to convey that which every soldier ought to know, and undoubtedly whets his reader's appetite, as he desires to do, for a fuller knowledge of the subject We should like to hear that the book is in the hands of every man on service, as we believe that its study will necessarily lead to a more serious attention to personal hygiene

The valuable work of the *Prehistoric Society of East Anglia* in connexion with Grime's Graves has recently been noticed in our columns,[1] and we now have before us Vol II , Part I , of the *Proceedings* of the Society (London H K Lewis and Co Price 3*s* 6*d* net) In addition to Mr J Reid Moir's presidential address, delivered at the end of 1914, on the Further Discoveries of Flint Instruments of Man Beneath the Base of the Red Crag of Suffolk, the volume contains several papers of interest, including the Occurrence of Palæoliths in North East Lancashire, by Dr T E Nuttall, and a Cave Site at Nettlebed, S Oxon, by Mr A E Peake Since this volume was published we learn that Mr Moir has been conducting a series of excavations in a brickfield to the north of Ipswich where some later Pleistocene relics have been discovered The human remains comprise small portions of occipital bones, the shaft of a female humerus, and a male femur, all in a well preserved condition

Within the compass of less than 100 pages Mr VERE MINGARD, in the *Story of Islington and Finsbury* (London T Werner Laurie Local History Series Price 1*s*) gives the reader a clear picture of the history and topography of an interesting part of London, whether in Saxon or more modern times The book is well illustrated with reproductions of old prints, and will certainly stimulate the interest of those who are unfamiliar with the story of our great metropolis ——In a companion volume Mr J F WOOD, B A tells the *Story of Manchester* (same publishers and price) from early times, when it was a small settlement on the banks of the Irwell, to the present day This book, too, is well illustrated, and makes interesting and stimulating reading

As a welcome reminder of the pursuits of peace appears a new and revised edition of *Roses and their Cultivation* (London W H and L Collingridge 1915 Pp 204 Price 3*s* 6*d* net) by the well known expert Mr T W SANDERS the editor of *Amateur Gardening* The book is well illustrated with coloured plates diagrams, and plans and among the new features is a chapter on the cultivation of roses as annuals A list, which the author states is by no means complete includes 1300 varieties of roses classified in alphabetical order under their respective types. Simple and practical instructions for every phase of rose growing are given

MAGAZINES

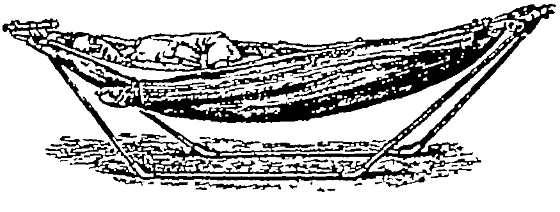
The Yellow Fever Bureau Bulletin Vol III , No 4 —We regret to learn that after the issue of this number the Bulletin will cease to appear The special funds which were collected in 1911 by the late Sir Robert Boyce to defray the expenses of the Yellow Fever Bureau at Liverpool are now exhausted consequently it is no longer possible to continue the publication of the Bulletin , but articles relating to yellow fever will in future appear in the *Annals of Tropical Medicine and Parasitology* Since the formation of the bureau three volumes of the Bulletin have been published as well as two large supplementary volumes containing the reports of various investigators who have been working during 1913 and 1914 under the Yellow Fever (West Africa) Commission, appointed by the Colonial Office Dr Harald Seidelin contributes to this number an article on the distribution and prevalence of yellow fever during the past two years and in it he points out that although in that period there has been a marked decrease in the number of cases reported, it does not follow that there has been a reduction in the endemicity of the disease He suggests that political and other conditions may have in some countries interfered with the influx of foreigners, non immunes, who are the chief source for supplying the typical cases by which the disease is usually recognised. It is maintained that further investigations of late have tended to confirm the views put forward by the late Sir Robert Boyce that yellow fever is endemic over a large portion of the West Coast of Africa Dr Seidelin, as editor, furnishes a paper on town planning in the tropics, with special reference to the prevention of yellow fever He also contributes two original articles, the first dealing with the histology of the liver in yellow fever illustrated by numerous coloured plates , the second comprises some notes on hæmatological technique A considerable portion of this number of the Bulletin is devoted to the furnishing of abstracts of many interesting books and papers relating to *yellow fever, pappataci fever, and dengue*, and appended is a bibliography divided into four sections—namely, (1) general , (2) yellow fever , (3) pappataci fever , and (4) dengue

We regret that so useful a journal as the *Yellow Fever Bureau Bulletin* should be allowed to die an untimely death for want of the necessary funds

New Inventions.

A BED STRETCHER

A STRETCHER that possesses the advantages of supplying comfortable support for the patient, is light and portable and when in use can be stood on wet ground, even in several inches of water or mud, without inconvenience to the sick or wounded man, should prove useful at the present moment A stretcher possessing these qualities has been brought to our notice by the patentee, Mr F Goddard, of 30, Coleman street London, E C , and we understand that it has already been put to practical use by the Belgian Government who have found it convenient and satisfactory, while the French and Italian Governments have the stretcher under consideration As will be seen from the illustration the apparatus consists of two inverted V shaped supports the free ends on each side being connected with each other, thus forming a cradle shaped framework A T piece is attached to the apex of the V shaped supports, and attached by rings to the ends of these cross pieces is a canvas sheet which stretches between them The framework of the stretcher is constructed of lengths of metal tubing, a detachable metal casting connecting the joints When not in use the stretcher folds up into a comparatively small compass It can be erected in a few seconds



LORD STRATHCONA'S LEPER CHARITY —It will be remembered that the late Lord Strathcona left a sum of £5000 for the purpose of founding a charity for the benefit of lepers A scheme sanctioned by the Charity Commissioners has now been issued and provides that the annual income shall be applied in one or both of the following ways—namely (1) In or towards maintaining a home to be used for the accommodation of British subjects in the United Kingdom suffering from leprosy , (2) in assisting the work of any persons, or society or company engaged in the relief of lepers in the United Kingdom The first three trustees are Mr John Burns M P who is appointed for life, and Sir A H Downes and Mr W T Jerred, C B , senior medical officer and assistant secretary respectively of the Local Government Board, who are appointed for the first five years The appointment of future trustees will be in the hands of the President of the Local Government Board then in office

HOMMEL'S HÆMATOGEN

Contains purified Hæmoglobin 80%, Glycerin 20%, and a trace of aromatic flavouring

Entirely Free from Antiseptics.

AN EFFICACIOUS REMEDY IN SEVERAL FORMS OF ANÆMIA, associated with constitutional diseases, and A POWERFUL RESTORATIVE when much blood has been lost by wounds sustained in action, by post-partum hæmorrhage, or in the course of surgical operations

IMPROVES THE GENERAL NUTRITION IN TUBERCULOSIS

PALATABLE, APPETISING, and free from any constipating tendency

☞ Please note that **HOMMEL'S HÆMATOGEN** is and always has been manufactured in **SWITZERLAND BY SWISS PROPRIETORS**, and that a continuous supply is assured The price has not been increased.

In prescribing please always specify HOMMEL'S Hæmatogen

ORGANOTHERAPY.

ENDOCRISINES.

TOTAL EXTRACT (prepared at freezing-point, and *in vacuo*) of Internal Secretory Glands.

We have employed the term ENDOCRISINES (from the Greek *ἔνδον*, internal, and *ἔκκρισις*, secretion) to designate generally our total extracts of internal secretory glands (thyroid, ovary, testicle, thymus, pituitary gland, suprarenal capsules, pancreas, liver, spleen, &c)

Before being introduced to the medical profession our products have been tested for more than two years in several clinics of eminent physicians, and in hospitals, with a therapeutic success under conditions in which other organotherapeutic preparations had failed Further, we are authorised to state, on the word of clinicians who have done us the honour of testing them (the experiments extend to several thousands of cases) that **owing to their activity and the reliability of their therapeutic effects ENDOCRISINES constitute a considerable progress in organotherapy**

The new process which we employ in the manufacture of our extracts, a process which is at the same time simple and rational, is based on the most reliable results of physiological research, which eliminates all the disadvantages of methods that have been employed up to the present, and also explains the superiority of ENDOCRISINES

WE HAVE AVOIDED ALL CHEMICAL TREATMENT OF THE GLANDS

"*No method of chemical treatment enables one to separate the active substance or substances, and simultaneously to exclude the inert substances (if such are present) of the internal secretory glands*

' *There is no reagent, however mild it may be, even atmospheric oxygen, the acids or alkalis in extreme dilution no solvent alcohol, ether, &c , the action of which will not diminish considerably or prevent, by the production of toxic compounds, the therapeutic action of fresh organs*

"Hence it followed that it is in the interests of medical men to reject as inadequate and dangerous all organotherapeutic preparations that have been manufactured by chemical means "

WE HAVE AVOIDED DESICCATION BY HEAT

" *The processes that utilise desiccation by heat are subject to two serious objections At comparatively low temperatures, between 20° and 40° C , desiccation takes place very slowly and the proliferation of micro-organisms is favoured and consequently also the formation of the products of putrefaction. As soon as a temperature of 40° C is exceeded the therapeutic activity of the organs decreases progressively, rapidly approaching the zero-point* "

By drying the organs that have been removed under the best possible conditions of asepsis in vacuo and at the temperature of melting ice, we obtain products that are free from all microbial contamination and do not differ from fresh glands except in the fact that they have lost their water, their entire activity being preserved because neither heat nor chemical reagents have destroyed these fragile elements

As a method of exhibiting the ENDOCRISINES we had the choice between compressed tablets, pills, or cachets

We have selected cachets for various reasons

In the case of organotherapeutic agents it is indispensable that their absorption should take place in the first portion of the digestive tract, compressed tablets and pills prepared by enveloping the active powder in some inert substance (gum, mucilage, gluten, &c), are unfavourable to this object being achieved and often reach the large intestine without having been disintegrated or absorbed

In the case of cachets, on the other hand, the absorption is certain the dose can be regulated strictly, and, further, it is possible to test the perfect state of preservation of the product as often as desired

The quantity contained in each cachet has been worked out for each gland in such a manner that, except in the case of special instructions being given by the medical attendant, the medium therapeutic dose corresponds to one or two cachets per diem **taken before the principal meals**

In order to avoid any confusion, the name and the dose of the organ contained are marked on each cachet

Summarising, ENDOCRISINES, total extracts of internal secretory glands offer at the same time the maximum of efficacy and reliability whilst being contained in the minimum of volume

THYROIDINE OVARINE (corpus luteum) **ORCHITINE** (testical) **HYPOPHYSIS** (pituitary)
SUPRARENAL KIDNEY MAMMA LIVER SPLEEN THYMUS

BILÉYL.

A Pure and Stable Extract of Fresh Ox-Gall, in the Form of Keratin-Coated Globules

Bile, the rôle of which having been unrecognised for a long time, has nowadays been completely elucidated, possesses therapeutic properties that are dependent on its function in the organism, and that may be represented as follows —

1 **An action antagonistic to intestinal putrefaction**
2. **Exito-motor action on the unstriated muscular fibres of the intestine**
3 **An anti-coagulating action on the intestinal mucus**
4. **Stimulating action (cholagogue) on the biliary secretion.**

From these various experimentally demonstrated modes of activity it has been possible for medical science to deduce conclusions defining the employment of bile It may be employed with advantage —

1 In all cases in which biliary secretion is either totally or partially suppressed
Icterus, Biliary calculus, or colic
2 In all cases in which this secretion is inadequate
Hereditary simple cholæmia, that latent widely spread and hereditary affection occurring in early life and manifesting itself by a **bilious 'earthy complexion, rusty spots urticaria, some pruritus, digestive disturbances such as constipation alternating with bilious stools, recurring attacks of jaundice, nervous disturbances, intellectual paresis, megrim, insomnia, circulatory disturbances, retarded pulse and dyspnœa, &c**

And finally **entero-colitis of the muco membranous type with constipation**

Bile in itself being eminently unstable and containing in addition principles that may be termed at least useless it was logical to try and isolate the active principles in a pure state

It is this property which is realised in BILÉYL a pure and stable extract of fresh ox gall, in the form of keratin coated globules, which only become dissolved in the intestines, where their action should come into play

Method of employment of BILÉYL

1	Adults	Six to eight globules a day to be taken towards the end of meals	2, 3 or 4 at a time
2	Children	From 3 to 6 years of age	2 globules a day,
		from 6 to 9 years of age	3 globules a day
		from 9 to 12 years of age	4 globules a day

THE LANCET.

LONDON SATURDAY, JANUARY 8, 1916

Lord Derby's Report on the Recruiting Scheme

LORD DERBY'S report on the recruiting scheme, the conduct of which was committed to him by the Government, appeared on Tuesday last, and as the actual figures have been issued by all the daily papers we need not repeat the analyses which are familiar by this time to our readers The winning of the war, rapidly and economically, is a national affair, it is the business of us all to help to this consummation by individual effort, by class organisation, and by common endeavour Therefore, the success or failure of Lord DERBY'S recruiting scheme is a matter of the first importance to medical men, most of whom will agree with us in feeling some sense of disappointment at the position A huge crowd of single men are holding back and furnishing by their dilatoriness a text for very unpleasant sermons

The total of recruits looks well, when it is remembered that the names have been obtained under a voluntary system But there are a large number of men actually medically unexamined among both the starred and unstarred, and it is a certainty that some of these men will be rejected when the various groups are called up and subjected to proper examination The question of medical examination will become very important, for a proportion of the new candidates have been rejected already for reasons of health and physique, and have presented themselves anew that they may earn an honourable discharge from their patriotic liability Close medical inspection may reduce the new recruits to a less imposing figure, but the starring of numerous occupations is what has most impeded the movement Lord DERBY, in his remarks upon the result, with which he is obviously not satisfied, pointedly declines to state what are in his opinion the industries indispensable to this country, but adds that if there is any further reservation of occupations the value of the recruits obtained must go down On learning from Lord DERBY'S report of the number of trades and occupations that have been starred it is inevitable that medical men should wonder why medical students should not have been starred, seeing that their value to the country in a few years' time will obviously be very large It would have been difficult however, for the medical profession to make any more definite stand in behalf of the cause of medical education than was actually made The War Office stated its intention not to discourage junior medical students from accepting combatant commissions, Lord DERBY informed an important official deputation, including the Presidents of the English Royal Colleges, that it was the duty of medical students, other than those in their fourth and fifth years of study, to join the forces, and the Director General of the Army Medical Service formally signified to the General Medical Council his agreement with Lord DERBY'S view

But it is impossible not to see that medical students had a far greater claim to be starred than many other young men, though we recognise with pride that their general feeling was wholly in favour of being permitted to take their own course and fight for their country at once But the question is still exercising the minds of many of our readers, for undoubtedly it is a reckless move to empty our medical schools of all save a few senior students, and to allow our professional roll to be without additions from the year 1918 to the year 1920, which is roughly the present position. Well may many of the teachers in our medical schools and the staffs of our universities ask why if a cowman is starred is not a medical student starred? The answer, of course, is perfectly obvious A cowman, a veritable cowman and not a person who calls himself a cowman so as to dodge his responsibilities as a recruit, is a person who is, *qua* cowman, of greater immediate use in the farmyard than in the ranks, while the medical student, drawn to a large extent from the stratum of society whence the best young officers are obtained, is urgently needed with the forces

We publish in another column a statement of the activities of the Central Medical War Committee, which, in close conference with the Medical Department of the Army, has worked out a scheme for recruiting medical officers

◆

The Measurement of Blood Pressure

THE progress of science has always been intimately connected with the introduction of instruments of precision The name of Dr. GEORGE OLIVER, whose life work we record in another column, will always be associated with instruments for the measurement of blood pressure For although others were earlier in the field in introducing methods capable of clinical application, he was one of the first to make that application and to facilitate it by the simplification and improvement of the apparatus required And a rich harvest of facts soon rewarded him, even though the interpretation of these facts is still to some extent in dispute The clinical value of observations on blood pressure is doubted only by those who have never made them It is true that the finger can detect some differences in pulse tension, but it is often entirely at fault, since it can only estimate total pressure, thus missing a high pressure if the volume be small In the same way although the hand can detect differences in temperature, it cannot replace the thermometer The sphygmomanometer has enlarged our ideas, cleared up difficulties in diagnosis, and helped in prognosis. This has naturally reacted on treatment. It has enlarged our ideas on "heart failure." The heart is adjusted to work at certain pressures, and though within considerable limits it can adjust itself to variations, those limits may be exceeded. In an acute infection blood pressure may fall dangerously low, and sensory stimuli do not produce the usual pressor result, though abdominal massage is still effective. It is the vasomotor system that is poisoned rather than the heart that is damaged. But the heart cannot carry on the circulation satisfactorily if the blood pressure is quite inadequate. Recognition of these facts has led to the problem being attacked through the vasomotor system by means which act peripherally, thus protecting the heart from secondary damage and needless or harmful stimulation. CRILE and LOCKHART MUMMERY take a similar view of the origin of surgical shock, though of late this has been disputed. There is the opposite condition in which the heart fails while the pressure is very high. In some cases where the pressure has been unduly high, perhaps for years, the heart fails because it can no longer work against an excessive resistance. But in others it is probable that the rise of pressure is compensatory. With diminishing output vaso constriction is necessary to lessen the size of the arterial bed. But this vaso constriction would only raise the blood pressure to its normal level again, it would not force it higher. Yet it is often a surprise to find with a feebly beating heart a pressure of 200 mm. or more. The recent work of STARLING and his school throws fresh light on this apparent paradox. The contractile force of a muscle depends upon and is proportional to its previous stretching, so that in its inception even cardiac dilatation is compensatory, and a rise of blood pressure will increase the stretching of the cardiac muscle. But it is a desperate expedient, for with overstretching complete failure may ensue. In a primary affection of the heart muscle this is particularly likely to occur, hence the liability to sudden and fatal syncope. This work has also thrown a new light on "back pressure," for a rise of venous pressure increases the filling and therefore the stretching of the right auricle. OLIVER was much interested in the measurement of venous pressure in man, and published a paper on the subject in 1898, long before its significance was grasped.

This new work explains what had previously been realised clinically—that the indiscriminate lowering of blood pressure by a frontal attack with vaso dilators is dangerous. In the early days of the sphygmomanometer there was too great a tendency to its use, just as there was a tendency to indiscriminate lowering of the temperature in the early days of antipyretics. A rise of pressure is a symptom just as surely as a rise of temperature. In all attempts at repair, however, the body may overshoot the mark, and it may become as imperative to lower pressure as to treat hyperpyrexia. The sphygmomanometer has aided in diagnosis in many ways. We may appeal to it if in doubt whether a hemiplegia is due to hæmorrhage or thrombosis, in the former it is always high, while in the latter it need not be and indeed seldom is. Perforation in typhoid fever causes a rise of pressure, while hæmorrhage produces a fall. A fall of blood pressure is occasionally a valuable sign of incipient or recrudescent phthisis. A great fall of blood pressure may occur quite early in Addison's disease. A marked fluctuation on change of posture in a patient with albuminuria suggests that it may be orthostatic in origin. A distinct difference of pressures in the two arms may be a sign of aortic aneurysm. As to prognosis, a continued rise in the already high pressure in cerebral hæmorrhage is of the gravest import. In chronic nephritis a raised pressure is necessary for adequate excretion, and cases in which it does not occur usually do badly. In pneumonia a continued but gradual fall of pressure is the rule. GIBSON found that any sudden rise before the crisis implied the onset of some complication, while a sudden fall was a warning of impending vasomotor paralysis, leading to heart failure. A rise of blood pressure in pregnancy has been found a valuable prognostic sign of the approach of toxæmia. But perhaps one of the most practical applications of the sphygmomanometer has been the recognition of the rise of blood pressure in later life, before any organic change has occurred in the arteries, and therefore while the case is still amenable to treatment. A busy man nearing 50 years of age, who finds himself getting unduly short of breath on slight exertion, and liable to vertigo, insomnia, "biliousness," or headache, may show no evidence of disease to ordinary physical examination, but the sphygmomanometer would probably reveal a blood pressure of 180 mm or more. If we meet this by putting the patient into the way of physiological righteousness rather than by depressor remedies, the results are often extremely gratifying. In this "pre sclerotic" stage we should pay more attention, as OSLER urges, to the peripheral field of the circulation "rather than tinker at the pump or the mains." And the peripheral circulation always received careful consideration in OLIVER'S work.

It is an interesting paradox that in medicine instruments of precision have a way, largely because of their educational influence, of diminishing the necessity for their own use. Thus the sphygmograph taught us many things about the pulse which could subsequently be recognised without its aid. The electrocardiograph was necessary to the detection of auricular fibrillation and to the explanation of its nature. But already we can sometimes diagnose this condition without it. To a certain extent the same is becoming true of the sphygmomanometer, but this does not diminish our indebtedness to the man who has familiarised us with its lessons.

Annotations

“Ne quid nimis”

THE NEW YEAR HONOURS

THE names of three medical men appear in the list of those on whom the honour of knighthood has been conferred. Sir George Andreas Berry is honorary surgeon oculist to the King in Scotland, an ex President of the Royal College of Surgeons of Edinburgh, and ophthalmic surgeon to the 2nd Scottish General Military Hospital. Sir Thomas Wright Parkinson is physician to Prince Louis of Battenberg and to the Countess Lytton Hospital for Wounded Sir Milsom Rees, C V O, is laryngologist to the King and Queen and to the Queen Mother Surgeon General Guy Carleton Jones, Director of Medical Services to the Canadian Expeditionary Force, has been made C M G Brevet Colonel William Westropp White, I M S, has been appointed to the Order of the Bath To the Order of the Indian Empire have been appointed as Companions Dr John Andrew Turner, of the Bombay Health Department, Lieutenant Colonel Robert Charles Macwatt, I M S, who already holds the Kaisar i Hind Medal, and Dr Suresh Prosad Sarbadhikary, of Calcutta A further knighthood in India has been conferred upon Dr Rai Kailash Chandra Basu Bahadur, of Calcutta The honours to members of the Regular Services are noted in another column and to the holders of all these well earned distinctions we offer hearty congratulation.

THE PROHIBITION ORDER AND BRITISH WINES

THERE appears to be a widespread but mistaken idea amongst the public and amongst tradespeople that the preparations known as British wines are non alcoholic, and there has been quite a brisk sale of these beverages during the hours prohibited by the recent Order Ginger wine apparently is the first favourite and the sense of warmth and invigoration which a glass of it gives is innocently attributed to the ginger present, while as a matter of fact the stimulus is due to alcohol The sale of this commodity and the drinking of it on licensed premises are therefore illegal at certain hours, since the Order refers to all alcoholic beverages The public has no means of deciding what beverages are alcoholic and what are not, and it seems to us to be an important omission in the Order that no definition of an alcoholic beverage is given We should have thought that it would have occurred to the authorities that the Order would be incomplete without a schedule As it is, the sale of alcoholic beverages of the kind we have described during prohibited hours has been carried on apparently unchecked. There is evidence also that the demand for these British wines has largely increased since at several shops it is a common experience to be told that the retailer is out of stock owing to the sudden popularity of this class of liquor On the other hand, some traders know perfectly well that such preparations are alcoholic, for they definitely refuse to sell them during prohibition hours But this attitude of compliance with the law is not shown everywhere, as this week we purchased at a grocer s shop at 3.30 P M, a bottle of raisin wine which on analysis proved to contain 10 per cent by volume of alcohol Similarly a sample of ginger wine was found to contain 11 61 per cent of alcohol Cordials, we know, are prepared on similar lines to British wines, but cordials are not fermented or fortified with spirit, and are generally labelled distinctly as non alcoholic If anyone will trouble to look up in an ordinary book of domestic recipes the section of home made British or fruit wines, he will find that in most examples the product is allowed to ferment for some time, and it is not surprising, therefore, that the alcohol, as in the cases we have quoted, grows to 10 per cent Further, in a number of recipes it is recommended to add to the partly fermented liquor brandy to the extent of 4 per cent This process recalls the preparation of port, for in this case the grape juice is allowed to ferment up to a certain point, and then the fermentation is stopped by the judicious addition of brandy Mulberries and bullaces thus make, we read in one book of recipes, “an excellent factitious port” In a similar way the following wines are prepared with or without the addition of sugar Gooseberry wine (British champagne), elder wine, damson wine, rhubarb wine, celery wine, parsnip wine, turnip wine, orange wine, cowslip wine, and so forth. It is a notorious fact that many teetotalers exhibit a preference for beverages which they regard as non alcoholic, but which on analysis prove to contain alcohol In some of the herb beers and in ginger beer, which is a fermented beverage, alcohol invariably occurs, and sometimes to the extent of from 4 to 9 per cent of proof spirit (50 per cent alcohol) It may be right to call these temperance drinks, but it would not be correct to describe them as non alcoholic The legal limit of alcoholic strength of temperance or non excisable drinks is 2 per cent proof spirit, and the unlicensed sale of beverages containing over this amount ought to be followed by penalties British wines are prepared on practically the same lines as foreign wines, and contain as much alcohol, therefore they cannot be exempted from the provisions of a Prohibition Order, and the teetotaler who finds satisfaction in the drinking of these wines should be disillusioned as to the source of his satisfaction Non abstainers know well that their feeling of satisfaction after drinking British wines is due to alcohol, and alcohol alone, and they have obtained what they wanted in prohibited hours because of the belief that British wines are necessarily non alcoholic That, as we have shown, is not the case

PROPOSED REFORMS CONCERNING VENEREAL DISEASE IN SWEDEN.

THE proposals of the Swedish Royal Commission on Venereal Disease with regard to the regulation of prostitution are based on the almost general admission that in its present form the regulation of prostitution by the police is neither humane nor effective enough The Commission has accordingly advocated the abolition of regulation in its present form, and has put forward the following proposals, which it is hoped will reduce the incidence of venereal disease without reacting too harshly on its victims 1 Abolition of the regulation of prostitution 2 Institution of an educational campaign among the public for the furtherance of knowledge of the infectious nature of venereal disease. 3 Assumption by medical men who examine and treat patients suffering from venereal disease of the responsible task of teaching these patients how to avoid further spread of the disease 4 Transfer of every expense in connexion with the examination and treatment of venereal disease, even among the well to do sometimes, to the sanitary authorities (this has already been the practice with regard to the hospital treatment of venereal disease, but the Commission's proposal extends this principle to the costs of diagnosis and of ambulatory treatment) 5 Notification of venereal disease by medical men with a view to its distribution throughout the country being ascertained (a modified form of notification has existed since Dec 30th, 1911) 6 Adoption of certain measures, compulsory if necessary, against sources of infection, with a view to the medical control and treatment of such cases These measures include (*a*) tracking down the source of infection largely by the help of notification by medical men, (*b*) compulsory sanitary control of persons coming under the vagrancy laws, and (*c*) supervision of certain persons who, in addition to being guilty of other offences, are suspected of suffering from venereal disease The Commission is in favour of the vagrancy laws being applied, as in the past, to those prostitutes who, "being unwilling to work honestly, have adopted dissolute living as their only or main means of support" Two of the Commission's members, Professor J E Johansson and Otto Westerberg, have dissented from the proposals referred to under (*a*), (*b*), and (*c*) The Commission has also advocated certain reforms in the hospital treatment of venereal disease,[1] and has recommended the insertion of penal clauses as a deterrent to the spread of infection Alterations in the laws dealing with such institutions as brothels are also suggested, as well as punishment for persons who encourage immorality in a manner calculated to provoke general disgust

QUARTAN MALARIA RELAPSE 42 YEARS LATER

Dr I van der Heijden records in the *Nederlandsch Tijdschrift voor Geneeskunde* (1915, vol ii, p 1680), the case of a labouring man, aged 64 years, living in Rotterdam, who developed a typical quartan malaria in February, 1915 The patient's blood contained the characteristic parasites, and the fever was rapidly cured by the exhibition of sulphate of quinine The writer remarks that cases of quartan malaria, never common, are unknown in the quarter of the town in which this instance occurred, as also is the anopheles, he concludes that the patient had a relapse from an old infection occurring when he was 20 years old At this period the man was working as a farm labourer near Leyden, and lived in the same house as a peasant who was suffering from quartan ague Dr van der Heijden's patient was attacked by the fever himself and suffered from it for about a couple of years He remembered that during this time he was able to work for periods of two and a half days, but then had to go to bed when the sweating stage supervened in the afternoon, next day he would be fatigued, but able to work After about two years he was given a medicine, presumably one containing quinine, that cured both himself and the peasant The quartan ague never returned till 1915 Dr van der Heijden comes to the conclusion that there can be no question of a new infection with the parasites of quartan malaria in this instance, he is therefore obliged to conclude that the case was one of a relapse 42 years after the original infection He notes that the patient had been living in Rotterdam for the last few years—he does not say for how many, and he presumes that he had the quartan parasites latent in his bone marrow all the time

THE "BROWN STUDY"

AT the present time there can be no more unpopular view, or shall we say no greater heresy, than to claim any advantage from the use of alcohol True, there are occasional evidences in the letters of soldiers that courage has been raised, drooping spirits revived, even successes achieved by the help of the rum ration, but even this moderate dose of stimulant is condemned by many persons of experience We wonder that these persons have never attempted to show that there is a state of mind which sometimes comes about in *pure sobriety* in which ideas flow readily, resolutions are quickly reached, speech finds its correct expression, and the physical well being makes itself unusually obvious—a state of mind which much resembles, in fact, that temporary exaltation which is most easily achieved by the moderate use of alcohol It is in such a state that truths dawn suddenly and clearly upon the unclouded intelligence It is in such a state that mighty actions are conceived poems born at a stroke, and mankind enlightened through the enlightenment of the individual. Because such a state is in rare individuals produced by moderate libations we have the saying "In vino veritas," but this clarity of the mental atmosphere can be and should be obtained without drinking It often is This happy result comes about through what is sometimes known as the "brown study' In this state of mind there is such a concentration of mental energy that the body is ignored The mind, on the other hand, is so working upon the subject which concerns it, is so intent upon its own affairs, that the external world is obliterated and any bodily discomfort that may have been pre existing is now negligible and unnoticed In the mental ardour of composition, be it literary, pictorial, musical, the creator is relieved from all bodily woes Thomas Hood forgets his lungs and Richard Wagner his poverty Over and over again in the history of men who have created things we find evidence of this glorious pre eminence of mental activity over all the detractions of poor surroundings or bodily ill health While they are in a "brown study" nothing can hurt them A similar exaltation is that which accompanies the mental concentrations of the Indian Mahatmas It is well known that these men can for long periods ignore even the usually necessary means of bodily subsistence, and it is claimed that in this state of spiritual exaltation powers of insight and of divination become possible to them that to the ordinary man may well seem to partake of the miraculous We need not believe the claim even while we see that the Indian fakir is able to utilise in a wonderful way the relationship between mental activity and bodily state And it is just this relationship which is not realised either with sufficient frequency or with sufficient thoroughness by the European to day The average man is too engrossed with his bodily pabulum, and in caring for the needs of the body he neglects the needs of the mind If the "brown study" were more often cultivated many people would be happier and more clear thinking would be done

---

[1] THE LANCET Dec. 11th 1915, p. 1308.

TEETHING AS A CAUSE OF SYMPTOMS IN INFANTS

THE problem of dentition in infants in one shape or another reappears from time to time in medical literature all the world over, and mothers and nurses appear to be, as a correspondent of THE LANCET points out this week, in entire agreement that teething is the *fons et origo* of that miscellany of ailments to which infants during the period of dentition are peculiarly prone It may further be asserted with some confidence that the majority of family practitioners are of the same opinion in a somewhat restricted sense The dissentients from this view are mainly to be found in the ranks of hospital physicians and specialists, but even among pædiatric physicians of the first rank there are diversities of opinion on this thorny question To give a few instances only, Dr A Jacobi, of New York, a pronounced sceptic and the Nestor of pædiatrics, caustically remarks in his "Therapeutics of Infancy and Childhood" (p 315) "There are, fortunately, practitioners who prefer making a diagnosis of the real condition of the ailing baby, and that and its improvement or cure comprise the main treatment I recommend for 'difficult dentition'" Dr Leonard Guthrie, whose opinion both as a neurologist and as a specialist in the diseases of children deserves the most respectful hearing, devotes in his "Functional Nervous Disorders in Childhood" an entire chapter to the disturbances associated with primary dentition. He discharges whole broadsides of good natured chaff at the expense of those who believe that the physiological process of dentition has pathological consequences He says on p 173 "I believe, therefore, that the ordinary phenomena of painful dentition are dependent on alimentary disturbances associated with a 'common cold,' and that dentition is painful because the gums become unhealthy" Dr G F Still, in a wholly admirable article on the same subject in his "Common Disorders and Diseases of Childhood," gives a long list of the symptoms which he ascribes to the process of teething, and concludes with the words "I am inclined rather to enlarge than to restrict my own conceptions of the rôle of dentition in producing disturbances of various kinds in infancy" Sir James Goodhart, in his "Diseases of Children" (seventh edition), says "Increased activity of all the physiological processes at work necessarily implies greater risks of friction between one organ and another, or even of regular breakdown Excessive energy, if not properly regulated or adequately expended, is liable to lead to an explosion of some sort or another' With such divergences of opinion between experts of unquestioned authority, how shall lesser men decide? It may, however, be remarked that the majority of authorities who write, at any rate authoritatively, on this problem and who as teachers have great influence in formulating opinion among practitioners, acquire the larger proportion of their knowledge from so called pathological experiences, for the greater number of children and infants whom they see are either sick or ailing On the other hand, it is interesting to note that the opinion of that now considerable number of medical men and women who act as officers to Infant Welfare Centres is almost unanimously in favour of the belief that teething is a common cause of disturbance to health, this fact is instructive, because at "Infant Consultations" the vast majority of the infants are relatively healthy[1] It has been claimed that dentition is a physiological process, and that since no physiological process should be accompanied by pain, dentition itself cannot be the cause of pathological phenomena. This syllogism is unsound in its major premise, in its minor premise, and in its general conclusion There is no true distinction between a physiological and a pathological process, both are designed to preserve life in the manner best suited to meet the existing conditions of the environment If they should happen to be accompanied by pain or other disturbance of bodily harmony so much the worse for the individual Pain is one of the most efficient means of protecting the body against existing dangers, and is in essence physiological Parturition is a physiological process and a distinctly painful one, especially in the case of the contracted pelvis, and so also may be the process of dentition in the contracted jaw of civilisation, as many can avow from personal memories of the cutting of the wisdom teeth During the period of dentition many symptoms develop either as a consequence of, or coincident with, the eruption of each tooth which must give the careful observer much food for reflection The almost invariable flush on the cheek of the healthy child, the running of the nose or the lacrymation in those less fit, the pharyngeal cough, the bronchitis or the diarrhœa in those of still poorer condition are best capable of explanation as the misdirected incidence of nervous energies, whether reflexly or by irradiation engendered by the eruption of the tooth, taking effect in organs or in situations of least resistance This may possibly explain why when any particular function has previously been disturbed there is apt to be a recurrence of the event during the period of dentition—why, in other words, the child always cuts its teeth "with bronchitis or diarrhœa," as mothers and nurses are wont to believe

ARTIFICIAL PNEUMOTHORAX IN THE TREATMENT OF PULMONARY TUBERCULOSIS

THE treatment of pulmonary tuberculosis by induction of pneumothorax was introduced by Forlanini, of Pavia, in 1882, and was later, but quite independently, advocated by Murphy, of Chicago, who in his address on the Surgery of the Lung at the annual meeting of the American Medical Association in 1898 reported 5 cases The method became popular on the continent, where a large amount of clinical and experimental work was done, of which the most important was the use of the water manometer by Saugman, of Christiania, to measure the intrapleural pressure In this country the method was neglected for many years, but recently has come into vogue In the *Journal of the American Medical Association* of Nov 27th, 1915, Dr T B Sachs has published an important paper on the results obtained by 24 American observers in 1145 cases The stage of the disease is reported in 1028 cases Of these, 88 7 per cent were "far advanced," 10 6 "moderately advanced," and 0 7 "incipient" 77 per cent were bilateral and 23 unilateral Cavities were present in 53 per cent In 23 per cent there were complications, such as laryngeal or intestinal tuberculosis, pleural effusion, or empyema. In about half of the cases no improvement was obtained, in 29 2 per cent temporary improvement followed, and in 21 7 per cent arrest or cure The large proportion of advanced cases must be taken into consideration in judging the results Sufficient data do not yet exist to show the ultimate results, as the method has been extensively practised only in the last few years So far it seems that permanent arrest is obtained in about 12 per cent, and a palliative effect of variable duration in about twice that number But it must be remembered that these figures are obtained from all the cases in which the method has been tried, and include cases in which obliteration of the pleural cavity by adhesions prevented, partially or completely, the induction of pneumothorax In cases in which the method is specially indicated the results are much better Thus the disease was arrested in about half of the unilateral cases Further, it must be remembered that the method is generally resorted to when all other treatment has failed The best results are obtained before the formation of extensive pleural adhesions, and before there is marked affection of the opposite lung or irreparable loss of health With gradual improvement of the technique and more careful selection of cases accidents during the production of pneumothorax have diminished The nitrogen should never be allowed to enter until the manometer shows, by sustained negative pressure and free oscillations, connexion with the pleural cavity Pleural effusion is the most frequent complication of the operation It occurred in 113 of the cases There is a considerable difference of opinion as to its effect on the progress of the case Pleural shock occurred in 26 cases, but in no instance was fatal Its symptoms vary from slight faintness to severe nervous disturbances, and fatal cases have been described. Gas embolism occurred in 3 cases, but this catastrophe should be almost impossible if the manometer readings before the admission of the nitrogen indicate that the orifice of the needle is in the pleural cavity Dr Sachs concludes that pneumothorax should be induced in all progressive cases of pulmonary tuberculosis which fail to respond to sanatorium treatment, regardless of the stage

[1] An instructive chart showing the influence of dentition on curves of weight in six cases is given (Chart 7 p 59) in the Report for 1914 by the Chief Medical Officer to the Infants Department of the Bradford Health Committee.

A LOST LIBRARY

THE library of the old Corporation of English Surgeons, so rudely dispersed in 1751, had been in process of formation ever since the days of Vicary or earlier In 1562, Thomas Vicary, serjeant surgeon to Queen Elizabeth, left by will to the Barbers Company "one booke called Guido and ii billes, ii bowes, ii shefes of arrowes, &c The Guido was a work by Guido de Cauliaco or Guy de Chauliac, whose "Cyrurgia" and other works were text books of that age In 1591 another serjeant surgeon, Robert Balthrop, wills his Guido to his servant, but leaves to "the companie of the Barbors and Chirurgeons of the Cittie of London the Chirurgery of that most excellent writer, John Tagaultius, the lattin booke and also the English translation that I have made thereof" This alludes to the "De Institutione Chirurgica' of Jean Tagault, published in Paris in 1543 He likewise leaves them "the Chirurgerie of the expert and perfect practitioner Ambrose Parev" Both these works he has "written into English for the love which I owe my brethren practising Chirurgerie and not understanding the Latin Tounge, and given them into the Hall for their daily use and reading both in Latin and English, and desiring that they may be kept fair and clean for my sake" These English translations have vanished as completely as the lost books of Livy, though Tagault's work was in its time so popular that it was translated into Flemish, Italian, and French, besides running through several Latin editions Not only are books mislaid, but they are quaintly misnamed in the sixteenth century Thus, another serjeant-surgeon "unto the Queen's Majesty, sick of body"—namely, Richard Ferris whose portrait appears on the extreme left of the kneeling surgeons in Holbein's well known picture—wills to the Company "a grete Pandack and another booke called a verroyce" This is probably the allusion of an unlettered practical man to the "Liber Pandectarum Medicinae' of Silvaticus, published at Venice in 1474, a gothic letter work, or to the same author's "Liber Cibalis et Medicinalis Pandectarum" (Naples, 1474), and to the "Medicina of Averroes, published in Venice in 1482 The latter work begins with the words "Incipit liber de medicina Aueroys' Hence "verroyce" We have more certain information as to the "Tables of Morus," which Mr Deputy Caldwell, in 1604, "freely gave to this Company to be distributed amongst the professors of chirurgery, freemen Some 500 copies were distributed, but the professors seem to have despised them They were thin folios of 32 pages, containing Latin tables and lists, and were probably treated as such gifts are wont to be even at the present time One copy of the "Tabulae universam Chirurgiam complectentes, ex eruditioribus Medicis collectae," fol, London, 1584, still exists in the library of the Royal College of Surgeons of England It is from the Pitt Collection, but the absence of names and graffiti on the fly leaves bears witness to original neglect During the seventeenth century a certain number of volumes, of which the titles are on record in the books of the Barber Surgeons' Company, were added to "the new library" In 1638-39, 64 volumes were chained, which would account for the 130 yards of chain bought at this time A chained book is given a tether measuring a trifle over two feet in length. At the end of the century the Company possessed Gerard's "Herbal," Stow's "Survey of London,' Dr Gwyn's MSS, Arris's five books on Surgery, the Anatomy of Cafferius Placentius, besides other works In the next 45 years we can imagine the Company adding to its collection a large number of books for books were then beginning to be published at frequent intervals These would include in time Cheselden's classical "Osteographia," the famous plates of Albinus, and the works of Heister It is curious to note that Hamilton, in 1794, describing an army surgeon's necessary library, which was to travel in bulk with the regimental baggage, mentions very few books printed prior to 1750 Modern medicine and surgery began only to make their appearance in print in the latter half of the eighteenth century when the Hunters, Cullens, Monros, Pringles, and other famous men rendered their profession illustrious. But the lost library none the less probably contained many classics such, for instance, as some 30 or so early printed books now rarely seen Curiosities also must have abounded on its shelves, as, for instance, works of astrology, of which De Bure gravely quotes many titles in his "Bibliographie Instructive" as late as 1764 Possibly the lost library contained some 600 volumes

THE IRRITABLE HEART OF SOLDIERS

In another column we publish an article by Dr C Percival White and Dr F Hernaman Johnson recording three cases of Graves's disease occurring in soldiers, and suggesting hyperthyroidism as a cause of the irritable heart of soldiers All medical men who have been attending officers and men from the Expeditionary Force have become acquainted with the so-called "irritable heart" It occurs frequently in men home from the front, and is usually only of a temporary character It is undoubtedly due to the constant strain of modern warfare, added to, in the case of officers, by the great sense of responsibility which is ever felt by them The accumulated efforts of the disturbing elements of active service produce a profound action on the nervous system generally, and the nervous mechanism of the heart likewise feels the strain Severe fright, great anxiety or worry, and great emotional disturbance have long been recognised as antecedents of Graves's disease, and it is not, therefore, a matter of surprise that this condition should develop in men invalided from the front The cases described by Dr Percival White and Dr Hernaman Johnson are of interest in drawing attention to this possibility, and will cause careful clinicians to look out for exophthalmos and the other symptoms characteristic of Graves's disease, but it remains for further observation before it can be definitely stated that this disease may explain many of the so-called irritable hearts For cardiac strain producing palpitation and irregular action of the heart is of common occurrence without the appearance of the other phenomena of exophthalmic goitre

ACUTE SPONDYLITIS

Acute spondylitis is a rare condition In the *New Zealand Medical Journal* Mr A Kinder has reported the following case A boy, aged 7 years, was admitted into hospital on April 10th, 1914, with osteomyelitis of the left tibia, which was opened and drained The temperature fell to normal, but a sinus remained It was curetted on June 17th, and, as progress was slow, the edges were bevelled off on Sept 23rd Three weeks later healing was well advanced and there was a granulating surface On Nov 18th the temperature rose to 103° F, without apparent cause, but next day it was normal On Dec. 1st the patient began to complain of pain in the back of the head and neck, and the temperature rose to 102° The neck was rigid and the head retracted, and when moved was supported by the patient with his hands in the manner typical of cervical caries Pain on movement became intense Examination of the pharynx was negative To eliminate cerebro-spinal meningitis lumbar puncture was performed, but the fluid was normal The rigidity of the neck increased and the pain rapidly spread to the upper dorsal spine Every few minutes the boy was thrown into a paroxysm of pain, the muscles being contracted in a convulsion like that of tetanus The pains shot into the shoulders and arms Morphia was given freely, as it was evident that the process was extending down the spinal canal and drainage offered no prospect of success The process became severe about the first lumbar vertebra—a point where two fairly fixed portions of the spine meet The temperature was typically septic The boy was conscious throughout the whole illness On Dec 14th lateral nystagmus was present, but there were no other signs of disease of the nervous system Lumbar puncture was again performed The fluid was under slight pressure but sterile Two days later the left pupil was contracted and the right semi-dilated, and both reacted sluggishly to light This symptom was evidently due to irritation of the sympathetic fibres of the first and second dorsal nerves The pain was as acute in the lumbar as in the cervical regions, showing that it was not due to tension but to irritation of nerve roots He steadily became worse and died on Dec 14th At the necropsy, on cutting down on the laminæ to expose the cord pus was seen to exude from the ligamentum subflavum between the sixth and seventh cervical vertebræ On removing the laminæ the extradural space was found filled with pus The suppuration extended upwards to the third cervical vertebra and downwards to the third lumbar No septic focus could be found in the bodies of the vertebræ The pus yielded a pure culture of staphylococci The vertebræ are comparatively exempt from acute osteomyelitis, the ends of the long bones seeming to offer a much more suitable nidus In this case the recrudescence of the disease eight months after the primary illness is noteworthy Discussing the treatment of acute cervical spondylitis, Mr Kinder recommends that when pain in the neck and pyrexia persist for more than 24 hours, with perhaps a septic focus elsewhere, the pharynx should be palpated If no cause can be discovered and lumbar puncture is negative a free incision should be made three quarters of an inch from the middle line on one or both sides, the laminæ exposed, and the muscles displaced outwards till the transverse process comes into view If pus wells up an attempt should be made to locate its origin with a probe If it comes from a joint this should be opened and the articular process clipped away if necessary If pus is welling up between the transverse processes an incision should be made at the posterior border of the sterno-mastoid

EXPERIMENTAL PELLAGRA

The causation of pellagra has been disputed for a long time, the two main views being that it is due on the one hand to a specific infection, and on the other that it arises from a deficiency of some essential element in the dietary In the United States of late there appears to have been an increasing belief that pellagra should be classed as a "deficiency disease," and evidence tending to support this has been found in the incidence of the malady in certain public institutions In order to test the possibility of pellagra being produced in white adults by a restricted one-sided diet, consisting mainly of carbohydrates (cereals) two medical officers, Dr Joseph Goldberger and Dr G A Wheeler, of the United States Public Health Service, have carried out an experiment in a public institution in the State of Mississippi, with the help of certain adult inmates who volunteered for the purpose, after the nature of the test and its possible consequences had been fully explained to them

Twelve white men were selected from these volunteers, and first of all kept under observation as to their health for about nine weeks before the experiment was begun It was found necessary, however, owing to "prostatitis," to eliminate one of the men The remaining 11 individuals were then placed on a diet consisting chiefly of cereals in the form of biscuits, corn bread, fried "mush" (maize that had previously been boiled), grits, rice, and collards, along with sweet potatoes, cabbage, brown gravy, sugar, syrup, and coffee No vegetable fats entered into the composition of the diet The cereals were of the best quality obtainable in the local market, and each man received on an average 3 32 pounds of food per day, having a caloric value of 2952 calories Three substantial meals were given each day Another group of 20 men were selected as controls, and they received the ordinary mixed diet of the institution The hygienic surroundings of the two groups were identical, the work allotted was the same for both, and the only difference between them was their dietary In the course of five months signs of pellagra developed in six of the 11 men placed on the restricted diet, while all the members of the control group remained in good health No case of pellagra had ever been recognised in this institution prior to the experiment The signs of the disease in the six men included dermatitis, along with nervous and gastro intestinal symptoms of a mild but marked kind It is noteworthy that the dermatitis in these cases was first observed on the scrotum of each patient It was a daily custom for the 11 men to be stripped and carefully examined, and it was in this way that the dermatitis was detected, later it appeared on the backs of the hands and elsewhere If, however, the men had not been stripped for examination the skin manifestations of the disease on the scrotum might have passed unnoticed, at least for some time It is therefore suggested that the affection of the scrotum in pellagra is possibly more common than has hitherto been believed The diagnosis of the malady was subsequently confirmed by experts called in to see the cases The results of the experiment seem to justify the conclusions of Dr Goldberger and Dr Wheeler that pellagra was caused in 6 out of 11 men who had consumed a restricted (cereal) diet for a period of about five months The details of this interesting experiment are published in the United States Public Health Reports for Nov 12th, 1915

THE INFANTILE MORTALITY OF VANCOUVER CITY

THE figures for infantile mortality in Vancouver City were at one time very high, but are now decreasing satisfactorily Mr F T Underhill, the medical health officer, stated on Dec 8th last that the figures in 1911 were 270, in the two years following 256 and 232, in 1914, 198, and that the mortality would be lower in 1915 The practical example of the medical profession may have counted for something as well as their advice A correspondent writes from British Columbia "'Physician heal thyself' has often been quoted to our profession and the retort has sometimes been hard to find, for, like our patients, we must all die, and ours is not one of the more healthy professions But at least in this part of the world we can keep our children alive, as the figures for 1911 just published show the mortality of the children of medical practitioners was less than that in any other group of 1000 children There were 1285 children of medical practitioners, with a mortality of 39, 1018 children of officers of army and navy, with a mortality of 43, 1018 children of barristers and solicitors, with a mortality of 45, 1083 children of men of no occupation with private means, with a mortality of 50, 1589 children of clergymen, with a mortality of 55"

THE DEVELOPMENT OF THE AMBULANCE TRAIN

IT is now a commonplace that disease claimed far more victims than the bullets of the enemy in all except the more recent wars, and next to ignorance of the elementary principles of hygiene, the greatest contributing factor was the herding together of the sick in camps close to the front where everything was subservient to the military necessity of the moment, and ample opportunity existed for handing on disease, once started, to the healthy soldiers. The way of avoiding these evils is to be found in the prompt removal of the sick and wounded from the fighting area to hospitals far behind the lines where ample leisure and equipment for their adequate treatment are available The history of the development of the means of transporting the sick and wounded is given by Mr E A Pratt in an interesting chapter entitled, "Railway Ambulance Transport," in his recent book on "The Rise of Rail Power"[1] The Crimea saw the first application of the railway to this end, when the wagons used for the transport of supplies on the little military line from Balaklava to the camp before Sebastopol were used on the return journey for the conveyance of the wounded, in the sitting posture it is true, but still with greater speed and comfort than ever before in the history of warfare In the Italian war of 1859 Dunant, who was then beginning to attract notice as the originator of the Red Cross, records that the wounded were taken by train from Brescia to Milan at the rate of a thousand a night, either lying on straw in goods or cattle trucks, or sitting up in third class carriages These experiences led to the suggestion by a Dr E Gurlt, in a pamphlet published in Berlin in 1860, to use hammocks suspended from the roof of the trucks, a suggestion which was not at once materialised owing to the unsuitability of the existing rolling stock It was therefore not until 1862, and in America, that the first ambulance car was planned and constructed by the Philadelphia Railroad Company This car was capable of accommodating 51 patients each on a stretcher arranged to slide in and out, with a seat for an attendant at each end of the car, which was also provided with a stove for heating soup or tea, a water tank, and a locker By using this car the patient could remain throughout the whole journey from field hospital to his destination on the stretcher on which he had been placed at the start This car was the precursor in all essential points of the luxurious ambulance train as we at present know it

AT the meeting of the Electro Therapeutical Section of the Royal Society of Medicine on Jan 21st, at 8 30 P M, a paper will be read on the Simpson Light by Dr E P Cumberbatch, who will also give a demonstration of the apparatus A note on the nature of this light, its mode of production and therapeutic properties, by Mr W D Harmer and Dr Cumberbatch, will be found in this issue of THE LANCET

SANITATION IN BILLETS AND CAMPS

By ADAM WHITE, M B , CH B , D T.M & H EDIN ,
D P H CAMB ,
LIEUTENANT R.A.M C (T) OFFICER COMMANDING SANITARY SECTION
2/1ST NORTH MIDLAND DIVISION

(*Concluded from p 42*)

CAMPS

THE presence of bodies of troops in canvas and hut camps raises many points of sanitary interest Under such conditions of life we have a reversion to an essentially primitive mode of existence The inhabitants of the camp are removed from the immediate sheltering care of more or less benignant sanitary authorities, the sanitation of the area which they are, for the time being, inhabiting is under their own jurisdiction, and the degree of sanitary perfection which is obtained largely depends upon the initiative which is displayed by those in command of the unit or brigade and upon the advice given to those responsible commanders by their accredited medical advisers Here it may be well to emphasise the fact that so far as sanitary effort is concerned the medical officer's duty is solely advisory, and that, of course, all executive authority resides in the hands of the combatant commanding officer But it is also necessary to state that the vast majority of commanding officers are only too ready to avail themselves of, and to follow the advice given them by, their medical officers, so that the sanitary perfections or imperfections exhibited by individual camps reflect largely the amount of interest which the medical officer takes in matters hygienic

General cleanliness and smartness of appearance are insisted on in the individual soldier as a matter of discipline, and a similar cleanly state as regards the camp area should be rigorously enforced No scraps of any kind should be allowed to lie about or to be cast upon the ground, and since there must be a certain amount of casual litter to be disposed of, it is essential that receptacles should be provided for its reception and temporary storage till it can be dealt with in the camp incinerator Such receptacles may take the form of small boxes or tins obtained from the quartermaster s stores, or they may be made from lengths of wood and wire netting, after the pattern of those found in public parks In the latter case the most convenient shape is that of a cylinder, approximately 3 feet long and 1 foot in diameter These receptacles should not be too numerous in any camp area, the right proportion being about one receptacle to each row of huts or tents Each receptacle should be nailed to a post at a convenient height from the ground

It is not always easy to convince camp commandants of the necessity for the provision of these receptacles, and in the case of camps which are obviously tidy their presence need not be insisted upon , but in instances where paper and other oddments are to be found about the camp ground and when one is told that such littering of the ground is impossible to prevent, the provision of such receptacles may be advocated as a remedy

Waste Water

In large canvas camps where a sewer connexion cannot be obtained the disposal of waste water from kitchens, ablution places, baths, &c , is often a difficult matter The problem we are here confronted with is that of the removal, without the help of sewers, of sullage water for a population of somewhere in the neighbourhood of 4000 men, a number of inhabitants equal to that contained in many of our smaller towns

There is nothing else which so mars the appearance of a camp as an inefficient system of waste-water removal In addition, a faulty disposal system produces water logging of the soil and fouling of the ground surface, and this often to such an extent as to cause grave nuisance and probably injury to health For these two reasons it is absolutely essential that the system of disposal should be as perfect as circumstances will permit

In the first place, we must remember that in the majority of schemes we are going to depend upon the porosity of the ground for the removal, and it is therefore necessary that the camping ground should consist of porous soil or that, at all events, it should be possible to reach a permeable stratum at a reasonable distance from the ground surface It will therefore be apparent that when a camp site is being selected due attention should be paid to this matter, and that, when tactical considerations permit, sites which are likely to present difficulties in this direction should be ruled out as being unsuitable Even if a stream is available in the neighbourhood of the camp it is unlikely that, in the case of temporary encampments, with the means of purification at our disposal, we should be able to produce an effluent which it would be permissible to pass directly into a water course

Preliminary Treatment of Waste Water

Laying aside, as being generally impracticable, direct passage into a stream, we may say that there are three principal methods by which, either alone or in combination, we can dispose of waste water These three methods are surface irrigation, subsoil irrigation, and disposal into soakage pits

Before the waste is in a state fit to be disposed of by any of these three procedures it must be treated in order to remove from it as much of its added impurity as possible and, in particular, any contained material which will increase the difficulties of disposal The principal ingredients which come under the latter category are grease and soap, the former predominating in kitchen waste and the latter being in excess in the case of water coming from ablution places Both these constituents militate against the success of any scheme by clogging up the interstices of the soil, and in the case of surface irrigation they have the additional disadvantage that they produce an unpleasant smell and an unsightly appearance of the ground In addition to the grease and soap, all gross impurities such as particles of meat and vegetables must be removed, and over and above this, it should be our aim to extract as much as possible of the finer suspended matter

A greater degree of purification than that outlined above it will seldom be possible to attain to, and it will therefore be apparent that our final effluent must be a highly impure fluid quite unsuitable for passage into a water course Anything in the nature of actual purification of the waste cannot be expected The ancient myth that gorse or bracken will act as an efficient grease and soap retaining medium is now happily exploded, and although in the case of the type of camp of which we are at present speaking it is eminently desirable to have the sullage water disposal system as simple as possible, it is little short of flying in the face of providence to rely on anything so childish as the typical gorse grease trap which has obtained the sanction of usage but certainly not the blessing of success

The unsatisfactory results which are obtained with this and with other similar primitive forms of trap led to the initiation of experiments, which were attended by varying degrees of success, with various combinations of coke breeze filters and sedimentation pits One has found that the end result which is obtained is influenced greatly by the character of the water as regards its degree of hardness, by the methods adopted in the cleansing of cooking vessels (whether much or little water is used in the operation and whether soda is employed), by the size of the filter chambers, by the character of the filtering medium used, and by the capacity of the sedimentation pits

Methods of Disposal of Waste Water

The following is a rough description of a system which was suggested by Captain J M Hamill, and which was installed in some of the camps occupied by troops belonging to the 59th Division

The waste water from the ablution benches and kitchen wash benches is led into a coke breeze or sand filter grease trap, thence through a sedimentation pit, and finally through a second coke breeze or sand filter Before it reaches the first trap the waste is passed through a sieve made of perforated corrugated iron in order to keep back gross particulate matter The filter traps are chambers made of wood well tarred and pitched, or of bricks set in cement or puddled clay Their approximate size is 4 feet long by 2 feet 6 inches broad and 3 feet deep They contain a cross partition so placed that the trap is divided into two compartments, one being 3 feet long and the other 1 foot long This partition reaches only to a point about 6 inches from the floor of the chamber, so that the two compartments communicate at their lowest points. Both chambers are filled to within 6 inches of the top with coke breeze or sand

As regards the ultimate disposal of the waste after its purification, the simplest method is undoubtedly that of turning it into soakage pits These pits should be made from 4 to 6 feet square, their depth being mainly governed by the distance from the surface of the ground at which a permeable stratum is reached, for if these pits are to work properly, and to be prevented from becoming mere stagnant and more or less permanent collections of waste water, it is essential that a porous stratum should be actually cut into The principal advantages of efficient soakage pits are that they take up little surface space, and that if they become fouled they can be filled in and fresh pits dug

Surface irrigation and subsoil irrigation are specially useful as adjuncts to a soakage pit Their great disadvantage is the comparatively large amount of land which is required for their efficient working This disadvantage is most evident when either of these systems is used alone When they are used to take the overflow from soakage pits the disadvantage is not so apparent, as in this case a large proportion of the waste is dealt with by the pit, and only a relatively small amount remains to be dealt with by the complementary system

When a sufficiency of sloping ground is available, either surface or subsoil irrigation can be applied with advantage, the trenches or drains, as the case may be, being made to follow the contours of the irrigation area These trenches or drains should have a depth and breadth of from 12 to 18 inches, and in the case of drains the channel should be filled in with tins which have been passed through the incinerator or with fair sized pieces of hard and well fired clinker The tins or clinker will allow passage for the waste and at the same time will support the replaced turf

Food Store and Kitchen Disposal of Refuse

In all camps the food store should be a separate and distinct structure from the kitchen In too many cases the one is only a part of the other The store should be placed as far as possible from latrines and urinals, but conveniently near the cookhouse Special attention should be paid to adequacy of space, to absence of damp, to lighting, and to ventilation, and means should be taken to prevent the access of flies to the food In the case of hut camps this latter end can be secured by the provision of fly proof gauze over the windows, but in the case of tents freedom from flies is not so easy to obtain However, much can be done by keeping the food as long as possible in its original packing and by covering exposed food with muslin or similar cloth

The means for cleansing cooking and eating utensils and for washing vegetables are often found to be markedly defective At least some form of bench, no matter how simple, should be provided for this purpose, and washing and cleansing should be allowed to be done only at the place appointed If possible, water should actually be laid on to this bench, and the waste should be run into a grease filter trap of the form described

In most camps kitchen refuse, which it would be wasteful to burn, is removed under contract, and for its reception pending removal, and also for the temporary reception of garbage which is to be burned, there should be provided suitable receptacles These should be cylindrical in shape, constructed of metal, watertight and covered In a recent memorandum it was recommended that camp kitchen refuse should be classified under four heads—i e , waste bread, bones and meat waste cookhouse and table refuse, tins and tea leaves, &c so that at least four such receptacles will be needed Frequent inspections are necessary in order to ensure that garbage which should be incinerated is not placed in receptacles meant to hold otherwise disposable material

All waste material which it is not profitable to retain should be burnt in some form of incinerator Most of the incinerators described in the various text books give good results, but the one which is most generally useful in the average camp is made in the shape of a square pit 4 feet high and 4 feet square There should be an opening about 15 inches square at ground level on each side, and just above these openings some simple form of fire grate to support the burning materials should be inserted In canvas camps these pits are best made of dry brickwork backed with turf, but in the case of hut camps the incinerator should be of a less makeshift type and should be constructed of 9 inch brickwork set in cement

Disposal of Excreta

Under camp conditions the methods which may be adopted for the disposal of fæces and urine are three in number—viz., water carriage, the use of bucket latrines, and the adoption of some form of immediate earth burial

In hut camps where a sewer connexion can be obtained water carriage should be installed the form of apparatus adopted being some variety of trough closet In hut camps in which for any reason it is impracticable to adopt water carriage bucket latrines should be used In this case the building intended to house the buckets should have a concrete floor which can be readily cleansed, and great pains should be taken to make sure that efficient ventilation is provided This is best secured by the provision of adequate openings situate under the eaves In canvas camps the excreta disposal system may be in the form of a bucket latrine, or some form of earth burial may be installed

Bucket Latrines

In the case of bucket latrines great care must be exercised in their method of use and in the manner in which the buckets are cleansed and emptied if these latrines are to be prevented from becoming an intolerable source of nuisance The buckets should be of convenient size to be placed under the seat of the latrine, they should be of metal, and water tight In order to reduce the risk of fæcal matter being deposited on the ground, there should be not more than one inch of clearance between the top of the bucket and the seat of the latrine, and, in addition, there should be some form of guard or stop to hold the bucket accurately below the aperture in the seat If at all practicable, the buckets should be provided with covers which can be clamped on, as then the buckets can be removed when full to the place where the excreta are to be disposed of instead of their being emptied into some form of cart in the immediate neighbourhood of the latrine itself Frequently, however, the buckets are not provided with covers and their immediate emptying takes place into a tank cart which is used for the transport of the excreta from the latrine to the place of ultimate disposal

Before being placed for use each bucket should be well smeared over on the inside with crude mineral oil, and there should be placed in it cresol solution (strength 1 ounce to the gallon of water) to a depth of 3 to 4 inches The object of these procedures is to discourage the presence of flies and to facilitate the emptying of the buckets No bucket should be allowed to become more than about half full before being taken out of use, and the provision of buckets should be on a scale sufficiently liberal to make this possible After emptying, the buckets should be swilled out with cresol solution Buckets or tubs used as urinals should be treated in the same manner as that outlined above

The Trench Latrine System

One great objection to the bucket system is that the bucket itself is, of course merely a stage in the scheme, for the buckets have to be emptied either in the vicinity of the place of use or elsewhere, and there is a considerable risk of spillage taking place during this operation The alternative system, that of immediate earth burial, has few of the disadvantages inherent to the bucket system, and, in addition there is no difficulty with regard to the ultimate disposal of the excreta, for the place of ultimate disposal coincides with the situation of primary deposition

There are many varieties of the immediate earth burial or trench latrine system, but the two most important are known respectively as the deep trench and the short, shallow trench The principal difference between these two varieties is that, in the case of the first named, the trench is anything upwards of 2 feet wide and 2 feet deep and as long as the ground available will allow and the requirements demand, while in the case of the last named the trench is from 1 to 2 feet deep, 1 foot broad, and 3 feet long

From practically all points of view the short, shallow trench is much the more satisfactory of the two varieties In the case of the deep trench it is practically impossible to ensure that the excreta will be covered with earth immediately after the act of defæcation, whereas in the case of the shallow trench it is comparatively easy to ensure this There is therefore less risk of nuisance from smell and of the carriage of disease by flies when shallow trenches are adopted

In addition, ground which has been the site of shallow trenches can be re used as a latrine area within a measurable time, whereas the deep trench leads to a more or less permanent fouling of the ground In other words, when using the shallow trench we are utilising the services of nature to the fullest extent, for, as has been shown by Dr George Reid, county medical officer of Staffordshire (lately divisional sanitary officer of the 59th Division), and others, fæcal matter deposited in the shallow trenches is rapidly dealt with by the organisms of the ground and cannot be recognised as excrement at the end of a period of time which varies for different soils, but which can be stated as being, on the average, about six weeks

The rate of disappearance of the fæces varies roughly inversely with the depth of burial, and at a certain depth disappearance does not take place at all, and the fæcal matter remains more or less in its original state for many years The best results are obtained when the trenches are made not deeper than 15 inches, and the working rule generally adopted is to adhere to a depth of 1 foot. When this specification is acted upon even paper, if of suitable texture, disappears in the same time as that required for the dissolution of the excrement The 1 foot of breadth is postulated as being a convenient space for a man to straddle over, and, moreover, this comparatively small space makes it as easy as is possible for the user of the latrine actually to cover the fæces with earth

In the digging of these latrines great care should be exercised to ensure that the turf is removed in one piece and that all edges are made sharp and straight and all angles clean cut The earth should be finely broken up and placed at the end of the trench, so that after each act of defæcation the user may cover the dejecta with earth. Small wooden scoops or small tins should be provided for this purpose, and it should be impressed upon all concerned that the efficient working of these latrines depends greatly upon the degree of conscientiousness which is displayed in the gradual filling in of the trench with earth. When the contents of the trench reach to about 4 inches from the ground surface the remaining earth should be filled in and the turf then replaced

Provision of Separate Urinals.

Where trench latrines are installed, distinct and separate urinals must be provided, as these latrines cannot be used for the disposal of urine. Many of the urinals which are described in the text books do not give satisfactory results, but the following is a description of a type which has adequately answered the purpose for which it is intended

A pit is dug 4 to 6 feet square and of such a depth as it is necessary to go in order to reach a permeable stratum The depth required varies, of course, in different localities, but it is generally possible to find a convenient situation in the camping ground at which porous soil can be reached within 10 or 12 feet of the surface This pit is filled to within, approximately, 2 feet of the ground level with burnt tins, large stones, or coarse clinker Four 9 inch drain pipes, one at each corner, are inserted so that their lower ends project some distance into the collection of tins and their upper ends protrude above the surface of the ground to a height of 18 to 24 inches The remainder of the pit is then filled in with earth and the surface re turfed When the work is completed only the four projecting pipes are visible The pipes should be treated daily with crude mineral oil, as in the case of latrine buckets

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND

THE WEEK'S SUBSCRIPTIONS

THE subscriptions to the *Belgian Doctors' and* Pharmacists' Relief Fund received during the week have been as follows —

	£	*s*	*d*
Pharmacists V T C Camp (collected at) per Commandant E A Atkins	4	11	6
Dr A E Causton	2	2	0
Mr A Chapman	0	11	11
Mr A E Mills	0	7	2
B M A South Indian Branch (per the Hon Treas)	5	6	10

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr H A Des Vœux, at 14, Buckingham gate, London, S W, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund crossed Lloyds Bank, Limited

NATIONAL HEALTH INSURANCE

Insurance Practice During War

A CORRESPONDENT of the *Leeds Post* complains with some justice of the hardship imposed upon medical men carrying on insurance practice for themselves and for others in circumstances of severe strain by the clerical work which such practice necessitates He states that the secretary of the North Riding Insurance Committee has been instructed to insist upon "all records, &c, being done as correctly, or even more correctly than in peace time, and to threaten that the patriotic absentee shall not receive his payment unless these records are kept" He adds that since war broke out it has been made compulsory that a patient should be seen on the day on which his certificate is given, so that a medical man may have to travel several miles in order to sign a certificate even though he may have had to visit the patient on the preceding day The writer, who signs himself "One of the Absentees,' makes two points with regard to these matters, urging, firstly, that it is not much encouragement to practitioners who enter the service of the Crown to know that they may lose their money for insured patients not through their patients being neglected, but through the records sent in with regard to them being defective, while those doing the work are also hampered in performing it, and secondly that medical men are being compelled to carry out strictly their part of a bargain which is not being fulfilled with equal exactness by those with whom they made it He urges in this connexion that practitioners are not receiving under the Insurance Acts the immunity from bad debts which was held out as one of the merits of the *insurance system* and as one of the inducements to them to serve on the panels Strictly speaking the term 'bad debts' is hardly applicable to the delayed payments made in instalments by Insurance Committees in view of the temporary financial circumstances which affect them No doubt the money owed by the Insurance Committees will in all cases be paid in full in the *end*, and though a business man might describe such debtors as "long winded," he would hardly treat their obligations as "bad debts" Undoubtedly, however prompt settlement was looked for when panel practice was instituted, and at any other time but the present it would rightly be insisted upon After the war the question will *properly* be raised if steps are not then taken to ensure the punctual receipt of fees, which in no cases are excessive in view of the work done in earning them With regard to the keeping of accurate records referred to above, it is fair to the Insurance Committees to point out that these are generally necessary with a view to the adjustment of the fees which will have to be paid in respect of the work done

The Certification Agreement in Ireland

The Insurance Commissioners have now issued to medical men who have signed the agreement with them as 'medical certifiers" a memorandum of instructions which, as was promised, modifies in important particulars certain of the clauses in the agreement itself The instructions in the memorandum are declared to be instructions issued under one of the clauses of the agreement, and thereby binding on medical certifiers The most important modification, from the point of view of medical ethics, is concerning the duty of a certifier who is asked to examine and certify for a person who is under the care of another medical man It is now definitely laid down "that a medical certifier *must refuse* to examine any such person if the certifier knows that he is being treated by *another medical certifier*, *unless* the latter has refused to issue a certificate" The exception stated in the last-quoted clause is intended to permit a member to ask a second medical man for a certificate in case he should think that his own medical attendant has unfairly refused to issue a certificate Moreover, "a medical certifier would also be justified in refusing to examine or issue a certificate to an insured or exempted person if he is satisfied and is able to satisfy the Commissioners that such person is the patient of a doctor who though not a medical certifier, is prepared to issue free of charge such certificates as may be required" The Commissioners appear to have taken pains to satisfy legitimate professional demands on this point In the event of a certificate being refused from any cause the certifier must forthwith notify the Commissioners With regard to complaints against certifiers the Commissioners may either deal with the matter by correspondence, refer it to a Local Medical Committee or investigate it at a special inquiry In any case the final judgment rests with the Commissioners The extreme penalty for an offence will be termination of the office held by the certifier but the Commissioners may inflict a monetary penalty for lesser offences, no fine, however, to exceed £5 Examples are given of the offences the Commissioners have in mind A paragraph is devoted to explanation of the difficult term "incapacity for work" In the case of short illnesses and during the earlier stages of prolonged illnesses, incapacity on the part of the insured person to follow his ordinary occupation would be the test of title to benefit according to the present general practice of Approved Societies and to the practice of Friendly Societies in the past. In the case of prolonged illnesses other considerations arise and it may be necessary to think of the possibility of the member taking up some other remunerative occupation, which could reasonably be regarded as open to him having regard both to the state of his health, his previous experience and training, local conditions, and other circumstances of the case The decision in such cases remains one of considerable difficulty On the whole, the memorandum is helpful and is evidently framed with a desire to work the new system fairly to all parties

BRIGHTON AND THE *INDIAN WOUNDED* It is officially known that no more Indian wounded are to be accommodated at Brighton Kitchener's Hospital occupying the original *Poor law* institution on the Race Hill has already been evacuated The patients have been gradually removed to the Royal Pavilion Hospital and discharged from there on convalescence Extensive alterations are now being made at Kitchener's Hospital with a view *to* adapt it for British wounded In round figures some *5000* Indian wounded have been treated at the Brighton *Hospital* and the very small percentage of deaths speaks volumes for the work of the distinguished medical staff

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE undermentioned have been entered as Surgeons for temporary service in His Majesty's Fleet —Dated Dec 18th William McHutchison Binning Dated Dec 23rd Roy Russell Kerr Dated Dec 28th Edward Pierce Llewellyn Hughes. Dated Dec 29th Robert Aitken Dated Dec 31st Joseph Patrick Fehily

The following appointments have been notified —Temporary Surgeons A. G Simmons and R R Kerr to the Victory, additional for Haslar Hospital, E G B Carpenter to the *Victory* additional for Portland Hospital, J Pratt, D S C to the *Victory* additional for disposal L S Fry to the *Bellerophon* G MacL Blair to the *Blake* G W M. Findlay J T Wilmot W McH. Binning, and W H Scott to the *Pembroke* additional for Chatham Hospital, J T E Evans to the *Pembroke*, additional, for disposal G Lillico to the *Conqueror* R K. Shaw to the *Wildfire* additional, to be lent for duty at R N.A.S Training Establishment, and T W Drummond to the *Donegal*

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel Ernest Brodribb is placed temporarily on the half pay list on account of ill health (dated Dec 18th)

The undermentioned Captains to be temporary Majors —Dated Jan 2nd Edward K. Martin, Joseph Dalrymple and Thomas R Elliott

Temporary and Honorary Captain William P S Branson to be temporary Honorary Major whilst serving with No 1 British Red Cross (Duchess of Westminster's) Hospital (dated Dec. 1st)

The undermentioned temporary Lieutenants to be temporary Captains —

Dated Oct 21st Charles G H Moore and Garnett W Twigg

Dated Nov 7th John T McCullagh

Dated Nov 10th Joe D Yule

Dated Nov 24th Fred A. R Hacker

Dated Jan. 2nd James Keenan

Dated Dec 10th Francis Robert Seymour to be temporary Captain.

The undermentioned temporary Lieutenants relinquish their commissions —

Dated Nov 9th Henry V Swindale

Dated Nov 10th William Wallace Woods

Dated Nov 28th Thomas Perrin

Dated Dec 17th George W Clark

The undermentioned to be temporary Lieutenants —

Dated Dec 1st George Herbert Simpson

Dated Dec 4th Alfred Tulloch Thompson Tom Stanbury Brook Allan Barrett John Alexander Harper, James Appleyard, Charles Henry Mossop James Norman Jackson Hartley, Basil Patrick Campbell, Colin Guy Hirst Campbell, Charles Booth Jones, Roland Sinclair, William Leslie and Matthew Wright Talbot

Dated Dec 6th John Francis Lambie, Solomon David Bridge, Frank Whinfield Bartlett Arthur Owen Evans Purser Davies, James Gordon Bell, Cecil Berry Frederick Hugh Young Augustin Pownall Fry, Edward Purcell, Rupert Cecil Lowe, Frederick Michael Bishop and James Arthur Venning

Dated Dec. 7th Robert Archibald MacNeill, Robert Townley Slinger Horace Mather William Arthur Berry, William Adam Paterson, John Charles Wilson James Christopher Wadmore and William Hackett Broughton

Dated Dec 8th George Burns Salmond Raymond Brewitt Taylor John Tudor Griffiths Daniel Colville Adam, Philip Dennis Scott Alexander Erskine Clark Herbert Andrew Watney, William Bird Loveless, and George Ellis

Dated Dec 9th Charles James Pentland John Thomas O Boyle Thomas Jones Lloyd Godfrey Russell Potter, Vyvyan Kendall Sadler, and David Irving Anderson

Dated Dec 10th Harry Joseph Cooper William Thomson Brown George Kee Everard Roney Grieveson William Joseph Spearing George Adams MacFarland John Clarke Mead James Milne Hermon, Charles Dyson Holdsworth Henry Joseph Keane Charles William Julius Dunlop William Joseph McLearn Baird William Hammond Hodgson John Christie Forbes Horace Macaulay Mills, Edward Wilfred Kirk, Robert Milne Lang and John William Hilliard

Dated Dec. 11th Ronald Campbell Cooke

Dated Dec 12th John Wesley Harvey

Philip Gordon Capon to be temporary Lieutenant whilst employed as a Dental Surgeon (dated Dec. 4th)

The undermentioned to be temporary Honorary Lieutenants —

Dated Dec 10th Basil Graves and William Henry Marshall

Overseas Contingents (Canadian Army Medical Corps) — H MacLaren to be temporary Captain (dated Nov 19th)

SPECIAL RESERVE OF OFFICERS

Royal Army Medical Corps

Captain Samuel Wright is placed temporarily on retired pay on account of ill health

Lieutenant Andrew C Cassells is placed temporarily on retired pay on account of ill health

Lieutenant (on probation) John B Cavenagh is confirmed in his rank

TERRITORIAL FORCE

Royal Army Medical Corps

East Anglian Field Ambulance Lieutenant Arthur E Tait to be Captain

East Lancashire Field Ambulance Major Thomas Holt, from West Lancashire Field Ambulance, to be Major

North Midland Field Ambulance Major Andrew E Hodder to be temporary Lieutenant-Colonel Captain Arthur E Tait, from East Anglian Field Ambulance, to be Captain

South Midland Mounted Brigade Field Ambulance Lieutenant William Vincent Wood to be Captain

South Midland Field Ambulance Lieutenant Walter M Cox *from* Attached to Units other than Medical Units, to be Lieutenant Lieutenant Walter M Cox to be Captain

Northumbrian Field Ambulance Captain Wilson H Morrison, from Attached to Units other than Medical Units, to be Captain Lieutenant Christopher Rogers to be Captain.

Northern General Hospital Lieutenant-Colonel Harry Littlewood, from the list of officers whose services are available on mobilisation, is temporarily placed on the permanent personnel The undermentioned Lieutenants to be Captains Balfour McKean and Robert P Anderson Captain Henry J Smith and Captain Basil H. C Lea Wilson are seconded for duty with East Anglian Field Ambulance.

Southern General Hospital The undermentioned Captains to be Majors Charles E Bean and Frederick G Aldous

London General Hospital Lieutenant Charles H. J Fagan to be Captain.

Home Counties Divisional Sanitary Section Frank Thomas Herbert Wood to be Lieutenant

London (City of London) Sanitary Company Henry Duguid to be Lieutenant Captain Charles J D Gair is restored to the establishment

London Sanitary Company Lieutenant Arthur G Whitfeild to be Captain

Highland Divisional Sanitary Section Alexander Fraser MacBean to be Lieutenant

West Lancashire Casualty Clearing Station Lieutenant Theodore H. Somervell to be Captain

Scottish General Hospital Lieutenant Patrick T Catto to be Captain

Supernumerary for Service with the Officers Training Corps — The undermentioned Lieutenants to be temporary Captains whilst serving with the Medical Unit of the University of London Contingent Senior Division, Officers Training Corps William Gilliatt and Richard D Maxwell

Attached to Units other than Medical Units —Captain William G Macfee to be Major Lieutenant Wilson H. Morrison to be Captain Frank Mainwaring Hughes and Edward Meyer de Jong to be Lieutenants.

NEW YEAR HONOURS

In the list of New Year Honours the following members of the services are mentioned Major George Andreas Berry R A M C (T), has been made a Knight, Surgeon General Sir James Porter, R N and Temporary Surgeon-General Sir William Watson Cheyne, R N were made Knight Commanders of St Michael and St George, and Surgeon General Guy Carleton Jones (Director of Medical Services Canadian Expeditionary Force) a Companion of the same Order In the Order of the Bath Fleet-Surgeon Arthur Gaskell, R N Surgeon-General William Henry Norman, R.N., Temporary Surgeon General Humphry Davy Rolleston, R.N and Colonel William Westropp White I.M.S received Companionships and in the Royal Victorian Order Surgeon-General Sir Anthony A. Bowlby was made a Knight Commander, and Staff-Surgeon Robert Joseph Willan R N a Member Lieutenant-Colonel Robert Charles Macwatt I M S received a C.I E

DEATHS IN THE SERVICES

Sir George Scott Robertson, K.C S I, the defender of Chitral Fort who died on Jan. 2nd, aged 64 was educated at Westminster Hospital Medical School and joined the Indian Medical Service in 1878 In the two following years he saw service in the Afghan War, and after acting as civil surgeon in the United Provinces became Agency Surgeon at Gilgit In 1891-92 he was the chief political officer with the Hunza Naga Expedition Most people know the story of the siege of Chitral Fort in 1895 and Sir George Robertson received the well-earned K.C.S.I for his courageous and successful defence of the fortress He was elected M P for Central Bradford in 1906.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN the 96 largest English and Welsh towns with populations exceeding 50,000 persons at the last Census, 6019 births and 5183 deaths were registered during the week ended Saturday, Dec 25th, 1915 The annual rate of mortality in these towns which had been 18 5, 17 1, and 15 7 per 1000 in the three preceding weeks, further declined in the week under notice to 14 9 per 1000 of their aggregate population, estimated at 18,136,180 persons at the middle of the year 1914 During the first 12 weeks of the fourth quarter of last year the mean annual death rate in these towns averaged 15 4, against a corresponding rate of 16 1 per 1000 in London The annual death rate in the week under review ranged from 5·7 in Ilford, 6 8 in Enfield, 7 3 in Acton, 7 4 in Leyton, and 7 7 in Barnsley, to 21 2 in Wolverhampton and in Dewsbury, 21 6 in Stoke on Trent 21 8 in West Bromwich, 22 7 in Middlesbrough, and 23 4 in Lincoln

The 5183 deaths from all causes were 279 fewer than in the previous week, and included 319 which were referred to the principal epidemic diseases, against numbers declining from 373 to 298 in the four preceding weeks Of these 319 deaths, 84 resulted from measles, 69 from whooping-cough, 68 from infantile diarrhœal diseases, 61 from diphtheria, 28 from scarlet fever, and 9 from enteric fever, but not one from small pox The mean annual death rate from these diseases was equal to 1·0 against 0·9 per 1000 in the previous week The deaths attributed to measles, which had been 93, 81, and 75 in the three preceding weeks, rose to 84, and caused the highest annual death rates of 2·0 in Ipswich, in Swindon, and in Leicester 2 1 in Gloucester, and 3 8 in Burnley The deaths referred to whooping-cough, which had been 63, 47, and 60 in the three preceding weeks further rose to 69, of which 20 were registered in London, 5 each in Manchester and Leeds, 4 in Birmingham, and 3 each in Lincoln and Sheffield The deaths from diarrhœa and enteritis (among infants under 2 years), which had been 98, 103, and 68 in the three preceding weeks, were again 68 in the week under review, and included 15 in London, 8 in Birmingham, and 4 each in Manchester and Darlington The deaths attributed to diphtheria, which had been 62, 74, and 65 in the three preceding weeks, further fell to 61, of which 9 occurred in London, 6 in Liverpool, 4 each in Stoke on Trent and Coventry, and 3 in Birmingham The deaths referred to scarlet fever, which had been 20, 22, and 19 in the three preceding weeks, rose to 28, and included 6 in London, and 2 each in Tottenham, Birmingham, Liverpool, Preston, and Sheffield The fatal cases of enteric fever, which had been 12, 11, and 11 in the three preceding weeks, fell to 9, and included 2 each in London and Leeds

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 3110 to 2582 in the eight preceding weeks, further declined to 2462 at the end of the week under notice 206 new cases were admitted during the week, against 278, 282, and 245 in the three preceding weeks These hospitals also contained on Saturday, Dec 25th, 1915 1465 cases of diphtheria, 48 of enteric fever 24 of measles, and 12 of whooping cough, but not one of small pox. The 1345 deaths from all causes in London were 71 fewer than in the previous week, and corresponded to an annual death rate of 15 5 per 1000 The deaths referred to diseases of the respiratory system which had been 516 438, and 357 in the three preceding weeks, further fell to 329 in the week under review, but were 59 above the number registered in the corresponding week of the previous year

Of the 5183 deaths from all causes in the 96 towns, 202 resulted from different forms of violence and 428 were the subject of coroners' inquests, while 1460 occurred in public institutions The causes of 50, or 1·0 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in London and in its 14 suburban districts in Manchester Sheffield Leeds, Bristol Hull, and in 58 other smaller towns Of the 50 uncertified causes, 19 were registered in Birmingham, 7 in Liverpool, and 2 each in Stoke-on Trent Southend-on Sea, Southport Preston, Bradford, Darlington South Shields, and Gateshead

In the 95 English and Welsh towns with populations exceeding 50 000 persons at the last Census, 6824 births and 5784 deaths were registered during the week ended Saturday, Jan 1st The annual rate of mortality in these towns which had declined from 18 5 to 14 9 per 1000 in the four preceding weeks rose in the week under notice to 16 6 per 1000 of their aggregate population estimated at 18 136,180 persons at the middle of the year 1914 During the 13 weeks of the quarter just ended the mean annual death rate in these towns averaged 15·5 against a corresponding rate of 16·2 per 1000 in London In the week under review the death rate ranged from 7 5 in Southend on Sea, 8 7 in Wimbledon 9·4 in Tottenham 9 7 in Ilford and 9·8 in Merthyr Tydfil, to 22 5 in Stockport and in Gateshead, 22 6 in Blackpool 22·9 in Leicester, 23 3 in St Helens, 24 5 in Bath, and 24 7 in Carlisle

The 5784 deaths from all causes were 601 in excess of the number in the previous week, and included 355 which were referred to the principal epidemic diseases, against 293 and 319 in the two preceding weeks Of these 355 deaths 100 resulted from measles, 80 from infantile diarrhœal diseases 79 from diphtheria, 60 from whooping-cough, 22 from scarlet fever and 14 from enteric fever, but not one from small pox The annual death rate from these diseases was equal to 1·0 per 1000, and coincided with that recorded in the previous week The deaths attributed to measles which had been 81, 75, and 84 in the three preceding weeks, further rose to 100, and caused the highest annual death rates of 1 2 in Nottingham, 2·0 in Grimsby, 2 1 in Gloucester 2 3 in Bristol, 2 9 in Stockport, and 3 4 in Leicester The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 103 68, and 68 in the three preceding weeks, rose to 80, and included 24 in London, 6 in Liverpool, and 5 each in Birmingham Leicester and Leeds The fatal cases of diphtheria, which had been 74, 65, and 61 in the three preceding weeks rose to 79, of which 15 were registered in London, 6 in Birmingham, 4 in Hull and 3 each in Stoke-on Trent, Liverpool, St Helens, and Oldham The deaths attributed to whooping-cough, which had been 47, 60, and 69 in the three preceding weeks, fell to 60 and included 12 in London 6 in Sheffield, 4 each in Birmingham and Liverpool, and 3 each in Coventry Leicester and Manchester The deaths referred to scarlet fever, which had been 22, 19, and 28 in the three preceding weeks fell to 22, of which 6 occurred in London, 3 in Manchester, and 2 in Darlington The fatal cases of enteric fever, which had been 11 11, and 9 in the three preceeding weeks, rose to 14, and included 3 in Southampton and 2 each in Bolton and Manchester

The number of scarlet fever patients under treatment in the Metropolitan Asylum Hospitals and the London Fever Hospital, which had steadily declined from 3110 to 2462 in the nine preceding weeks were 2464 on Saturday, Jan 1st. 254 new cases were admitted during the week, against 237, 245, and 206 in the three preceding weeks These hospitals also contained on the same date 1490 cases of diphtheria 51 of enteric fever, 31 of measles and 12 of whooping-cough but not one of small pox The 1503 deaths from all causes in London were 158 in excess of the number in the previous week, and corresponded to an annual death rate of 17 4 per 1000 The deaths referred to diseases of the respiratory system which had declined from 516 to 329 in the four preceding weeks, rose to 346 in the week under notice but were 216 fewer than the number in the corresponding week of the previous year

Of the 5784 deaths from all causes in the 96 towns 238 resulted from different forms of violence and 525 were the subject of coroners inquests while 1676 occurred in public institutions The causes of 71, or 1 2 per cent of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in Manchester Leeds Bristol West Ham, Bradford, and in 64 other smaller towns Of the 71 uncertified causes 18 were registered in Birmingham 10 in Liverpool, 4 in Preston and 3 each in London, Bootle, Southport, and Rochdale

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2 345 500 persons at the middle of 1915 904 births and 765 deaths were registered during the week ended Saturday, Dec 25th, 1915 The annual rate of mortality in these towns which had been 22 4, 18 7, and 19 7 per 1000 in the three preceding weeks, fell to 17·0 per 1000 in the week under notice During the first 12 weeks of the fourth quarter of last year the mean annual death rate in these towns averaged 17 9 against a corresponding rate of 15·4 per 1000 in the large English towns Among the several towns the death rate during the week ranged from 10 8 in Hamilton 11 5 in Kirkcaldy and 12 4 in Ayr, to 18·9 in Coatbridge 23 5 in Perth and 25 4 in Greenock

The 765 deaths from all causes were 123 fewer than the number recorded in the previous week, and included 50 which were referred to the principal epidemic diseases against numbers declining from 87 to 64 in the three preceding weeks Of these 50 deaths 16 resulted from measles 12 from scarlet fever 11 from infantile diarrhœal diseases 8 from diphtheria 2 from whooping cough and 1 from enteric fever, but not one from small pox The mean annual death rate from these diseases was equal to 1 1, or 0·1 per 1000 higher than that recorded in the large English towns The deaths attributed to measles, which had been 31 24 and 24 in the three preceding weeks, fell to 16 and included 4 each in Glasgow and Coatbridge, and 3 each in Greenock and Hamilton The deaths referred to scarlet fever, which had been 11 20, and 11 in the three preceding weeks, numbered 12 of which 4 occurred in Aberdeen and 2 each in *Glasgow, Edinburgh, and* Dundee The fatal cases of diarrhœa and enteritis (among infants under 2 years) which had been 17, 12, and 8 in the three preceding weeks rose to 11, and included 5 in Glasgow and 2 in Aberdeen The fatal cases of diphtheria which had been 21, 19 and 14 in the three preceding weeks, further fell to 8, and included 2 each in Glasgow, Dundee, and Paisley The deaths from whooping cough were registered in Glasgow and Greenock, and that from enteric fever in Glasgow

The deaths referred to diseases of the respiratory system, which had declined from 322 to 208 in the four preceding weeks further fell to 155 in the week under notice, but were 20 in excess of the number recorded in the corresponding week of the previous year The deaths from various forms of violence numbered 28, against 17 and 38 in the two preceding weeks

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of last year, 991 births and 782 deaths were registered during the week ended Saturday, Jan 1st The annual rate of mortality in these towns, which had been 18 7, 19 7 and 17·0 per 1000 in the three preceding weeks, rose to 17·4 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death rate in these towns averaged 17·9, against a corresponding rate of 15 5 per 1000 in the large English towns In the week under review the death rate ranged from 7 6 in Falkirk 10·5 in Clydebank, and 11 8 in Perth, to 24·8 in Coatbridge 27·0 in Hamilton, and 28·0 in Greenock

The 782 deaths from all causes were 17 in excess of the number in the previous week, and included 74 which were referred to the principal epidemic diseases against numbers declining from 87 to 50 in the four preceding weeks Of these 74 deaths, 26 resulted from measles, 21 *from* scarlet fever, 11 each from diphtheria and infantile diarrhœal diseases and 5 from whooping-cough but not one from enteric fever or from small pox. The annual death rate from these diseases was equal to 1·6 against 1 0 per 1000 in the large English towns. The deaths attributed to measles, which had declined from 31 to 16 in the four preceding weeks, rose to 26, of which 6 occurred in Greenock, 5 each in Coatbridge and Hamilton, 4 in Glasgow, and 3 in Edinburgh The deaths referred to scarlet fever, which had been 20 11, and 12 in the three preceding weeks, rose to 21, and included 7 each in Glasgow and Aberdeen and 4 in Edinburgh *The fatal cases of diphtheria* which had declined from 21 to 8 in the four preceding weeks rose to 11 and comprised 4 in Glasgow, 2 each in Edinburgh, Paisley, and Kirkcaldy and 1 in Leith The deaths of infants (under 2 years) from diarrhœa and enteritis which had been 12, 8, and 11 in the three preceding weeks were again 11 in the week under review and included 6 in Glasgow and 2 in Aberdeen The 5 *deaths referred to* whooping-cough were slightly in excess of the average in the earlier weeks of the quarter, but showed no excess in any particular town In addition to the above deaths a fatal case of typhus was recorded in Dundee

The deaths referred to diseases of the respiratory system, which had declined from 322 to 155 in the five preceding weeks were again 155 *in the* week under notice and were 55 below the number registered in the corresponding week of the previous year The deaths from the several forms of violence numbered 32 against 38 and 28 in the two preceding weeks

---

HEALTH OF IRISH TOWNS

In the 27 town districts of Ireland with an aggregate population estimated at 1,212 380 persons at the middle of the year 1915 383 births and 396 deaths were registered during the week ended Saturday, Dec 25th, 1915 The annual rate of mortality in these towns, which had been 21 8 20·0, and 22 2 per 1000 in the three preceding weeks fell to 17·0 per 1000 in the week under notice. During the first 12 weeks of the fourth quarter of last year the mean annual death rate in these towns averaged 18 2 against corresponding rates of 15 4 and 17·9 per 1000 in the English and Scotch towns respectively The annual death rate for the week mentioned was equal to 17·0 in Dublin (against 15·5 in London and 17·0 in Glasgow), 18 1 in Belfast 17 7 in Cork 20·2 in Londonderry, 19·0 in Limerick and 20 9 in Waterford, while in the 21 smaller towns the mean death rate did not exceed 13·5 per 1000

The 396 deaths from all causes were 120 fewer than the number registered in the previous week and included 38 which were referred to the principal epidemic diseases against 37 and 46 in the two preceding weeks *Of these* 38 deaths 19 resulted from measles 8 from infantile diarrhœal diseases 4 from whooping-cough 3 *from* scarlet fever and 2 each from enteric fever and diphtheria but not one from small pox. The *mean annual* death rate from these diseases was equal to 1·6 against corresponding rates of 1·0 and 1[illegible] per 1000 in the English and Scotch [illegible]

deaths attributed to measles, which had been 15, 14, and 18 in the three preceding weeks, numbered 19 in the week under review and comprised 12 in Dublin and 7 in Belfast The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 12, 9, and *10 in the three preceding* weeks, fell to 8, of which 6 were registered in Dublin The fatal cases of whooping cough which had been 11, 5 and 8 in the three preceding weeks, fell to 4, and included 3 in Belfast The 3 deaths from scarlet fever were slightly below the average in the earlier weeks of the quarter and showed no excess in any town The fatal cases of enteric fever were registered in Dublin and those of diphtheria in Dublin and Bangor

The deaths referred to diseases of the respiratory system, which had been 144, 122, and 121 in the three preceding weeks, further fell to 94 in the week under notice Of the 396 deaths from all causes 109, or 28 per cent., occurred in public institutions, and 8 resulted from violence The causes of 19 or 4 8 per cent, of the total deaths were not certified either by a registered medical practitioner *or by* a coroner after inquest, in the large English towns the proportion of uncertified causes did not exceed 1 0 per cent.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of last year 502 births and 564 deaths were registered during the week ended Saturday, Jan 1st The annual rate of mortality in these towns, which had been 20·0, 22 2 and 17·0 per 1000 in the three preceding weeks, rose to 24 3 per 1000 in the week under notice During the 13 weeks of the quarter just ended the mean annual death rate in these towns averaged 18 7, against corresponding rates of 15 5 and 17·9 per 1000 in the English and Scotch towns respectively In the week under review the annual death rate was equal to 24·0 in Dublin (against 17·4 in London and 15·9 in Glasgow), 25 1 in Belfast 32 0 in Cork 13 9 in Londonderry 16 2 in Limerick, *and* 22 8 *in* Waterford, while in the 21 smaller towns the mean death rate was 24 1 per 1000

The 564 deaths from all causes were 168 in excess of the number in the previous week, and included 60 which were referred to the principal epidemic diseases against 46 and 38 in the two preceding weeks Of these 60 deaths, 22 resulted from measles 12 from whooping-cough 10 from scarlet fever, 9 from infantile diarrhœal diseases, 6 from diphtheria, and 1 from enteric fever, but not one from small pox. The annual death rate from these diseases was equal to 2 5, against corresponding rates of 1·0 and 1 6 per 1000 in the English and Scotch towns respectively The deaths attributed to measles, which had been 14, 18, and 19 in the three preceding weeks, rose to 22, and comprised 9 each in Dublin and Belfast, and 4 in Cork The deaths referred to whooping cough, which had been 5, 8 and 4 in the three preceding weeks, rose to 12, of which 4 occurred in Limerick and 3 in Dublin The fatal cases of scarlet fever, which had been 4, 7, and 3 in the three preceding weeks, rose to 10, and included 5 in Belfast and 3 in Cork The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 9, 10, and 8 in the three preceding weeks were 9 in the week under review, and included 4 in Dublin and 2 in Belfast The 6 deaths referred to diphtheria comprised 4 in Cork and 2 in Dublin, and were 3 in excess *of* the average in the earlier weeks of the quarter The fatal case of enteric fever was registered in Belfast

The deaths referred to diseases of the respiratory system, which had declined from 144 to 94 in the four preceding weeks, rose to 152 in the week under *notice* Of the 564 deaths from all causes, 155 or 28 per cent, occurred in public institutions, and 20 resulted from violence. The causes of 27, or 4 8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest, in the large English towns the proportion of uncertified causes did not exceed 1 2 per cent

---

PRESENTATION TO DR. T J. WALKER.—Dr Walker who in August of last year, was presented with the freedom of the city of Peterborough, was on Dec. 22nd last the recipient of his portrait in oils painted by Mr Fiddes Watt A R S A The presentation, which took place in the Fitzwilliam Assembly Rooms, was made by Mr G C W Fitzwilliam who said that Dr Walker was admired for his professional abilities, was looked upon as one of the greatest citizens of Peterborough and was loved as *friend*, companion, and neighbour Accompanying the portrait was a book containing the names of 750 subscribers and bearing on the title page the following inscription "On the completion of the eightieth year of his age, his friends and neighbours presented Dr Thomas James Walker Doctor of Medicine, Fellow of the Royal College of Surgeons Justice of the Peace Volunteer Decoration, his portrait painted by Fiddes Watt, A R S A [illegible] a token of their esteem and affection [illegible]ember, 1915"

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND

To the Editor of THE LANCET

SIR,—The wind up of the year brings back to my mind the events which occurred a year ago at the same period, when you gave me the opportunity to expose to you the sufferings of my countrymen, the crimes committed in Belgium, and the sad situation in which so many Belgian doctors and pharmacists were living

Under the management of a medical committee, you immediately called upon the spirit of fellowship of the members of our corporation, and I enjoyed the moving consolation to find that your call was responded to from all quarters of the world

On behalf of my colleagues in Belgium, although I have been unable for a good while to communicate with them, I grasp this opportunity to deeply express to you, to the chairman and gentlemen of the committee, my heartfelt thanks for the lasting effort made by all of you during the past year The voices of all those you have so generously assisted in their sufferings, of whom you may have saved life, cannot yet reach you, the Germans are still there to prevent it Later on, when we shall be free, when we shall be able to think again and to express openly our feelings, they will tell you themselves—better than I could—the greatness of your assistance

I will only now beg you to accept the gratitude of the Belgian doctors and pharmacists—the gratefulness of their little children, which must bless you at the distance

I am, Sir, yours faithfully,

C JACOBS

London W, Dec 31st, 1915

TREATMENT OF TRYPANOSOMIASIS

To the Editor of THE LANCET

SIR,—As is the case with so many protozoal infections of man, successful treatment entails keeping the disease under control and the infection reduced to a minimum for a prolonged period, probably at least two years In trypanosomiasis derived from infection in West Africa, Uganda, Congo, &c, this can be attained by subcutaneous injections of atoxyl or its equivalents, aided, perhaps, by antimonial preparations for shorter periods Rhodesian trypanosomiasis, however, does not yield to atoxyl or other arsenical preparations It can be kept under control by antimonial preparations, but these as a rule can only be administered in sufficient doses to be effective by intravenous injections The number of available veins is limited and in any case continued intravenous injections are painful and partake of the nature of an operation It is true that in one case we kept a patient in fair health by this method for three years, during which time 250 intravenous injections were given but this is exceptional Our object, therefore, has been, if possible, to find some form of antimony preparation that could be readily administered without causing tissue necrosis, abscess, or severe pain when injected subcutaneously, or gastric disturbance when given by the mouth Administration by means of enemata has failed For an occasional intravenous injection there is little difficulty Tartar emetic, metallic antimony, antiluetin are all successful, and no trypanosomes will be found in the peripheral blood for 3–5 days after such administration If these preparations are administered subcutaneously, whether given well diluted or in hypertonic saline solutions, or in the case of metallic antimony in Lambkin's medium, local severe pain usually persists for days, and sometimes tissue necrosis ensues

In view of this, we consider that it is worth while calling the attention of those who have such cases to deal with to a preparation of antimony oxide, and to quote in this report one case in the hopes that a more extended trial will be given to this preparation and the results recorded —

On admission, on Nov 3rd, the patient, aged 20 (Rhodesia), was treated with atoxyl subcutaneously and antiluetin by the mouth Trypanosomes were always easily found in peripheral blood and varied from one or two up to 20 to 200 leucocytes Intravenous injections of tartar emetic were in addition used and for two or three days after such injections no trypanosomes were to be found, but on the third or fourth day they would again appear to the extent of 6–24 in 200 leucocytes On Dec 8th 30 minims of Martindale's injectio antimonii oxidi (equivalent to 1 20th grain tartar emetic) were given subcutaneously daily, and no trypanosomes were found till the 14th and on that day 2 per 200 leucocytes were found whilst on the 15th the number had increased to 3 per 200 leucocytes On the 16th 30 minims of the injection of antimony oxide were given twice a day, and since then no trypanosomes have been found These injections are painless, can be repeated, and cause no more trouble than, say, a morphia injection

An extended use of this drug is well worth while, as present methods, even if they control the disease, are painful, and few will stand them for a prolonged period In cases of Rhodesian trypanosomiasis hitherto treated by other methods the termination has always been disastrous Possibly the preparation we have employed may give as satisfactory results as atoxyl does in other cases of trypanosomiasis, and it is in the hope that it may have an extended trial or that other preparations may be suggested that we have brought the matter forward —We are, Sir, yours faithfully,

THE SUPPLY OF MEDICAL MEN FOR THE ARMY

To the Editor of THE LANCET

SIR,—What is apparently meant to be a warning appears in your issue of Dec 25th—namely, that the medical profession will only have itself to thank if the present scheme of volunteering fails and conscription has to follow And yet I venture to suggest that were a plébiscite of the whole profession taken only a very small minority would be found to vote against complete mobilisation The civil doctor differs from other volunteers in the fact that he is to all intents and purposes ready for duty, and does not require the months of training necessary for combatants

There is no use blinking our eyes to the fact that the present scheme is manifestly unfair to many of us, say, for instance, as between a man of 42 and one of 46 The latter is not wanted, however fit he may be, or however keen, but his slightly junior neighbour is in a most difficult position. If mobilisation of the whole profession took place, and it was recognised that every man would have to do his share, either at home or abroad, all the apparent hardship would cease. A man of 50, if of reasonable health, is perfectly able to do duty in a military hospital or at a camp. But the civil doctor has a very definite duty to the public, and it ought to be possible for short periods of service, say three months, to be arranged, and let this period be the same for everybody.

I say, further, that if only as an example of what every decent minded Britisher ought to be doing now—namely, to be wearing the King's uniform, then the sooner all of us are mobilised the better. Lest this should be vetoed on the ground of expense, then let pay be given only when on actual military service.

I am, Sir, yours faithfully,
STANLEY MELVILLE.

Devonshire place, W. Dec 27th, 1915.

To the *Editor of* THE LANCET

SIR,—I have read with much interest and appreciation the leading article on the supply of medical men for the army in THE LANCET of Dec 11th, 1915, but if you will permit me to express the opinion, this most urgent question has yet to be considered on broad and logical lines. Naturally the Army Medical Department has but one object in view—the securing of as many medical men as possible for the army. This attitude is quite understandable, and I am sure that the profession is of one mind as to the absolute necessity of the adequate treatment of the sick and wounded sailor and soldier, but the ranks of the profession are limited and cannot be elastically expanded as can those of a combatant army.

The great problem which awaits solution is therefore this, How can the just demands of both soldier and civilian be met by a limited and an already depleted profession? There is only one answer to this question—by organisation, and this organisation must be made to apply to both the civil and military aspects of the problem.

In your article you refer to the steps which are being taken to organise the civilian medical service. Equally and perhaps even more important is it that an earnest effort should be made to adjust the military medical service to the conditions of the hour, for there cannot be a doubt that the medical material which has recently flocked to the service of the War Office is not employed on strictly economical lines. By economy I mean economy in the skill and time of the medical men employed. And the true reason of this economic waste is to be found in the fact that the Army Medical Department is endeavouring to meet the medical and surgical needs of an army of over 3,000,000 men in war time on the same administrative lines as those of an army of some 250,000 men during the time of peace.

The sooner it is realised that with the limited medical supply at our disposal this cannot be done without serious injury to the civil population, the sooner will the solution of our difficulties appear in sight. In other words, far reaching modifications of administrative methods are urgently needed.

If one aspect of the question is considered—i e, the administration of our home military hospitals—it is at once evident that there is economic waste of professional skill and time in the employment of medical men (*a*) in posts the duties of which consist almost wholly of non-medical administrative work, (*b*) in clerical work, such as writing up the non medical details of history, case sheets, &c, and (*c*) in the work entailed by the present cumbrous method of invaliding.

I have only alluded to one or two of the numerous aspects in which the ramifications of a peace time administration tend to economic waste when it is sought rigidly to apply it to the wholly different conditions of a great war.

In conclusion allow me to assure you that only a compelling sense of what is due to both soldier and civilian has prompted this letter.

I am, Sir, yours faithfully,
PRO PATRIA.

Dec. 19th, 1915.

A TRENCH FOOT-WARMER

To the Editor of THE LANCET

SIR,—For those most liable to trench foot owing to a less robust heart and circulation there are three requisites (in addition to a dry skin under waterproof stockings or a layer of grease) for protection against the threatening condition and for its early treatment. (1) Surface heat for the wet boots and leggings to make them conduct warmth to the skin instead of conducting it away, (2) ventilating heat to dry them, and (3), if possible, some supply of restorative heat for the abdomen and spine.

For these purposes a simple apparatus has been devised which one man can use at a time. A larger model has been planned for simultaneous use by batches of six if desired. Its principle is a novel modification (to be referred to as "thermospiry" under its other hygienic, medical, surgical, and general applications) of that of the central heating system, with the difference that, to suit the trench limitations as regards fuel, the entire heat production from a small supply of it is utilised for the sufferer's benefit with hardly any loss. That principle provides for two warm air circulations (1) one for the heated air (within a closed system, as in the radiator), and (2) a general ventilating circulation for the hot air which has passed through the "heater" to rise from under the feet into the investing atmosphere confined under impervious clothing. For relative air tightness the following provisions are made. 1. After donning an oil skin overcoat (provided at the nape with a wide outlet tube to discharge the slightly contaminated air away from the mouth and nostrils) the man steps into a tarpaulin bag and stands in it on two footplates (perforated to drain away any water and to concentrate the hot ventilation from the heater situated below the standing plate upon the wet boots and leggings). 2. He then draws up and straps the bag across the middle of the thighs—over the trousers and under all his coat skirts. These are then gathered over the bag by an outer strap above the knees. The investing air thus confined is kept in circulation in the first place by the ascending hot draught (an outer air supply tube passing in over the edge of the bag down to the heater), but that circulation is much activated by foot paddling, arm swinging, and shoulder shrugging. The "closed circuit" consists of two connected metallic air chambers (thin copper, tin, or aluminium). One is an outer skin surrounding the heater with its contained fuel. The other stands up between the foot plates as a flat hollow shield to warm the calves. Between them is arranged an air pumping box (or tambour) under a treadle worked by the right or the left toes in alternating spells, for the purpose of increasing the heat of the shield according to the rate of the air revolutions through the heating chamber below

A more complete description must be reserved for a further note after the scheme, if approved, has undergone any improvements recommended by the Royal Army Medical Department

We are, Sir, yours faithfully,
William Ewart

RETENTION OF URINE IN THE ADULT, WITHOUT APPARENT CAUSE, AS A PATHOGNOMONIC SIGN OF TUBERCULOUS MENINGITIS

To the Editor of The Lancet

Sir,—Dr D W Keiller Moody's interesting article in your issue of to day on retention of urine as a symptom of tuberculous meningitis recalls a paper by Dr S Vere Pearson, which appeared in the *Clinical Journal* in December, 1902, entitled "Tuberculous Meningitis in Adults Occurring as a Terminal Event in Chronic Pulmonary Tuberculosis" Though Dr Pearson's paper deals primarily with tuberculous meningitis in connexion with pulmonary tuberculosis, his remarks also have reference to meningitis complicating tuberculous lesions other than pulmonary He divides the cases into three classes Those in which the signs of tuberculosis are (1) Well recognised and advanced, (2) recognised but not advanced, and (3) indefinite or absent Dr Moody's article is chiefly concerned with the cases which fall under the third heading, which is the most important one from a diagnostic standpoint For the onset of meningitis is a matter of grave concern when it occurs in a patient who is enjoying good or even moderate health, whereas its appearance in a patient with advanced pulmonary tuberculosis merely hastens the end He gives notes of four adult patients, who subsequently developed tuberculous meningitis, in whom there was retention of urine without apparent cause, and he has come to look upon it as a pathognomonic sign of tuberculous meningitis *in adults*

Dr Pearson came to the same conclusion, for he writes —

> Retention of urine occurring in a patient with chronic pulmonary tuberculosis, whether the disease is advanced or only slight, should always suggest tuberculous meningitis where no local cause for the *retention* can be found, for it is often one of the earliest symptoms of the disease

Both authors also state that the importance of the symptom resides in the fact that the ordinary evidences of meningitis are usually absent in the tuberculous meningitis of adults, at all events in the early stages of the disease Thus two observers, working independently, have described an association which should prove of much value in diagnosis, and the publication of Dr Moody's article will lead to a greater confidence in accepting its significance

I am, Sir, yours faithfully,
H E Symes Thompson

⁂ In another column the sad news is announced of the death of Surgeon D W K Moody on H M S *Natal* —Ed L

ILLUMINATION IN OPERATIONS

To the Editor of The Lancet

Sir,—In his letter on this subject in The Lancet of Dec 4th, 1915, Mr J L Aymard points out the advantage of a concentrated light in a partially darkened room as contrasted with a diffused light which is only partially concentrated I think most surgeons will agree that a properly concentrat light is the ideal one for operating theatres, but the has hitherto been some difficulty in obtaining a sui able light The fault to be found with the illumin tion in most operating theatres at present is that t light is either not sufficiently concentrated upon t operating field, or else that it is too easily obstruct by the surgeon and his assistants The disadvantag of a powerful light just over the operating tab (the most usual form of lighting) are that the he from such lights is exceedingly uncomfortable the surgeon, and that dust may easily be shak off the pendant into the wound. The use of powerful arc light fixed outside the theatre, t rays from which are reflected by mirrors, to so extent solves this difficulty, but has the serio objection of being very complicated and easily p out of order

I believe by far the most suitable light is t of the type which we have installed at St Mar Hospital It consists of three motor boat he lights of 50 candle power each, fitted in t ceiling, two of them being in the corners of t ceiling at one end of the room and one half w between the two corners of the ceiling at t other end of the room The beams from all th are made to converge on to a circle about 1½ f in diameter at the operating table The lamps fixed and the table is moved to get the light in correct position The light is intense, resembl brilliant sunlight, and is cold and without shado As the rays come down from the ceiling at angle of about 45° the surgeon and his assista can move about freely without obstructing light The rest of the room is in semi darkne This is an ideal arrangement, giving an inte light where it is wanted without worrying the e since only the operating field is illuminated T lamps are air tight, and the reflectors only requ cleaning once a year, while the lamps require attention The light is controlled by ordin switches The installation is quite simple, all t is required being three good motor headlights wh give a parallel beam of light, and a transforme cut down the current to 6 volts The latter necessary on account of the extremely small f ments required to enable the whole of the light be brought within the focus of the reflectors T whole system only cost about £20 It has now b in use at St Mark's Hospital for 18 months, has proved an entire success

I am, Sir, yours faithfully,
J P Lockhart Mummer

Jan 1st 1916.

THE DEMAND FOR LOCUM-TENENTS

To the Editor of The Lancet

Sir,—May I through your columns appeal practitioners requiring a locum tenent during th absence at the front or otherwise not to be mis by representations that owing to the scarcity men they will have to pay 9 or 10 guineas a w to secure a deputy As a matter of fact, owin the generous way in which retired and elderly pr titioners have come forward, to a certain num being available on return from the front, and others ineligible for military service, the supply locum tenents is at present in excess of the dema and trustworthy men can be had at 7 guinea week Those requiring help should refuse to the excessive fees in some cases demanded, es cially by men who ought to be doing their d with the army —I am, Sir, yours faithfully,

Percival Tur. E

Adam-stree Adelphi London, W C Jan. 3rd 1916

Obituary

GEORGE OLIVER, M D LOND , F.R C.P LOND

WE regret to announce the death of Dr George Oliver, which occurred at his residence at Farnham, Surrey, on Dec 27th, 1915 He was born in April, 1841, being the second son of Mr W Oliver, a surgeon, of Middleton in Teesdale, Durham He was educated at Gainford School, and having decided to adopt his father's profession he proceeded to University College, where he had a brilliant academic career which culminated in his taking the gold medal at the M.D examination of the University of London in 1873 Even in these early days he gave evidence of a truly scientific conception of his work, and he always had a deep admiration for William Sharpey, who was professor of physiology at University College in those days Subsequent to this he started practice at Redcar, he only stayed there a few years, and in 1875 went to Harrogate, where he speedily developed a large practice, first as a general physician and subsequently as a consultant He spent altogether 33 years at Harrogate, and was recognised as the highest authority there in the special branch of practice associated with that town During the later portion of this period he used to reside in London or in Sidmouth during the winter, only living at Harrogate for the season, in 1901, however, he acquired a beautiful home in Surrey, where he spent the winter months, and it was not until 1908 that he entirely relinquished his Harrogate work This freedom from the *claims of a* busy practice during a long period of each year enabled him to prosecute original research, which he loved, some of this was carried out at the Physiological Laboratory, University College, but a good deal in his private laboratory He was always clever at any mechanical device, and most ingenious and resourceful in overcoming difficulties

He wrote extensively not only on the Harrogate waters, but also on urine testing, the fourth edition of his 'Bed side Urine Testing" was published in 1889, and his originality here was shown by the invention of testing papers known as "Oliver's test papers' But it was always the blood and its circulation that most attracted his attention, and one instrument after another dealing with this branch of science were brought under the notice of the medical world, his hæmacytometer, hæmoglobinometer, arteriometer, and sphygmometer are instances He will be especially remembered for his work in connexion with blood pressure, he it was among British physicians who chiefly insisted on the importance of estimating blood pressure in diagnosis, and the instruments of precision he introduced for this purpose will live long to keep his memory green His book on "*Studies* on Blood Pressure ' rapidly passed through two editions, and at the time of his death he was nearing the completion of a third edition, in which the book was practically rewritten It is to be hoped that this work may ultimately be published

Another branch of medical science to which he devoted himself was that relating to the ductless glands and he published papers on the suprarenal, thyroid thymus, and pituitary bodies In this direction he was perhaps best known by the remarkable paper, published in conjunction with Professor Sir Edward Schäfer on the suprarenal gland This really formed the foundation for all the enormous amount of subsequent work on the adrenal body which has resulted not only in the discovery of the functions of this formerly mysterious organ, but also in the discovery of the active principle adrenaline, one of the greatest boons to suffering humanity Although Addison many years ago had dimly conjectured the use of the suprarenal capsule, it was not until Oliver and Schäfer published their famous paper that any clear light was thrown upon the subject, and Dr Oliver at once grasped the practical application of the discovery

In 1887 Dr Oliver was elected a Fellow of the Royal College of Physicians of London, and a few years later he founded there, in memory of his old master Sharpey, the lectureship which now bears the name of the Oliver Sharpey lectureship Dr Oliver was most suitably chosen as the first lecturer under this trust, when he took as his subject "Studies on Tissue Lymph" (1904) He had previously filled the position of Croonian lecturer at the same College (1896), which gave him the opportunity of bringing prominently before the profession the importance of a study of blood pressure This does not by any means exhaust the list of his writings, for he contributed largely to the journals and also to standard works, such as "Quain's Dictionary of Medicine," in which he wrote articles on constipation and on other ailments of the bowels He was thus a man with wide attainments His recreations included photography, in which he became an expert, and until the last few years he took his exercise mostly in the form of cycling He was never a man of strong physique, but in spite of this he continued to live an active and strenuous life About five years ago he had an attack of hæmatemesis, from which he fortunately quickly recovered For about a month before he died he suffered from some bronchial catarrh, and the coughing so occasioned evidently strained the weak spot in his gastric lining On Christmas night he was again seized with bleeding, which no remedy could check, and two days later he peacefully passed away

His great aim throughout life was to make medicine a more exact science than he found it, and none can deny that he succeeded in this great endeavour The keynote of his success, both at the bedside and in the laboratory, was untiring perseverance, he was never satisfied with anything that was imperfect, but went steadily on, altering and improving his inventions until they gave absolutely correct results It was the same with his writings, he wrote and rewrote each sentence until it was absolutely clear so as to express his meaning in the fewest possible words He never hesitated to change his views when necessary, and much of what he wrote in his earlier editions was consequently amended as his apparatus were perfected and gave him results which corrected those obtained earlier with less perfect instruments He was a man of a singularly sweet, genial, and unselfish disposition, which endeared him alike to his patients and his friends He will be greatly missed not only in the scientific world but also by the large circle of his personal friends in Yorkshire, London, and Surrey

During the time he was at Redcar he married Alice, the only daughter of Mr J Hunt, of Barnard Castle, by whom he had one son and one daughter who survive him His first wife died in 1898 In 1900 he married again, Mary, daughter of Mr W Ledgard, of Roundhay, Leeds, and she survives him Dr Oliver was buried in the churchyard of the peaceful little church at Tilford on Dec. 31st, the church which he used faithfully to attend

The War.

THE CASUALTY LIST

THE following names of medical men appear among the casualties announced since our last issue —

Killed

Major F M Johnson, 6th Field Ambulance, Australian A M C, obtained his M D at Edinburgh in 1888, and prior to the war was in practice at Melbourne, Australia

Captain A G Miller, attached to the 12th Middlesex Regiment, was in England, from Melbourne, when war broke out, and joined the R A M C

Captain A. B Thompson, R A M C, 3rd East Lancs Field Ambulance (T F), graduated M B, B Ch Oxford, 1914, and was a student at the London Hospital

Lost in the Explosion on H.M S "Natal"

Staff Surgeon Alfred O Hooper, R N, graduated M B, Ch B in 1903 at Edinburgh University, and was at one time assistant surgeon at the Leicester Infirmary

Surgeon D W Keiller Moody, R N, graduated M B, C M in 1900 at Aberdeen University, and held appointments at Peterborough Infirmary, the Central London Infirmary, and Addenbrooke's Hospital, Cambridge, and was a surgeon at Haslar Naval Hospital before joining the Grand Fleet

Died of Wounds

Lieutenant W F Thompson, R.A M C, was educated at St Bartholomew's Hospital, and obtained the M.R C S, L R C P Lond in 1912

Lieutenant M B Patel, I M S, attached to the 7th Rajputs, obtained the L R C P, L R C S Edin in 1908

Wounded

Lieutenant R C McMillan, R A M C, attached to the 14th Welsh Regiment

Captain J E Brydon, R A M C (T F), attached to the R F A, Northumbrian Division, Ammunition Column (T F)

Captain T W Wylie, R A M C

Lieutenant A Wylie, R A M C, attached to the Royal Garrison Artillery

THE HONOURS LIST

The following promotions and appointments of medical men in recognition of their services in connexion with the operations of the Army and Navy are announced —

To be C B, Military Division, additional member

Fleet Surgeon A Gaskell, R N

To be C B, Civil Division, additional members

Surgeon General W H Norman, R N

Temporary Surgeon General H D Rolleston, R N

To be K C M G, additional members

Surgeon General Sir J Porter, R N, LL D, K C B

Temporary Surgeon General Sir W W Cheyne, Bart, R N, C B

To be K C V O

Surgeon General Sir A A. Bowlby, K C M G

To be M V O (4th Class)

Staff Surgeon R J Willan R N V R

The *Military Cross*, for "gallantry and devotion to duty in the field," has been conferred upon—

Temporary Captain Henry James Burke, R.A.M C (attached to the 1st/8th Battalion West Yorks Regiment (T F))

For conspicuous gallantry on Nov 8th 1915, near Turco Farm A sergeant in the front line had his leg crushed by the blowing in of a dug-out, and Captain Burke found immediate amputation necessary In order to save time he crawled across the open to get his instruments while the enemy turned a machine gun on to him In spite of their fire he returned the same way and coolly performed the operation in the trench while the enemy were shelling it heavily

Temporary Captain Bartholomew James Hackett, R A M C (attached to the 7th Battalion Suffolk Regiment)

For conspicuous gallantry and devotion to duty at Loos on Oct 2nd 1915 When the battalion to which he was attached had suffered very heavy casualties and had run out of dressings, Captain Hackett brought up a fresh supply from the dressing station, crossing over about 1000 yards in the open He has frequently attended the wounded under fire, and has shown great bravery

MENTIONED IN DESPATCHES

The following officers connected with the medical profession, and occupying the indicated positions with our armies, are recommended in Sir John French's despatch dated Nov 30th, 1915, and issued from the War Office Jan 1st, 1916, "*for gallant and distinguished service in the field*" It is a matter for deep regret that some of them are no longer with us

DEATHS AMONG THE SONS OF MEDICAL MEN

The *following* sons of medical men must be added to our lists of those who have fallen during the war —

Second Lieutenant A G Scott, 2nd Battalion, 3rd Duke of Wellington's *Regiment*, elder son of Mr G H Scott, of Sheffield

Corporal A F Hudson, 16th Battalion, Canadian Scottish, eldest son of Dr A B Hudson, of British Columbia (late of Cobham, Surrey)

R T Wight, Loyal Suffolk Hussars, only son of Dr T H T Wight, of Harvard

Lieutenant L H White, R N, H M S *Natal*, second son of Dr Hale White of Wimpole street, London

Second Lieutenant C S Lee, Royal Engineers, only child *of* Lieutenant Colonel W A Lee, late I M S

Lieutenant Commander T B Murray, R N, H M S *Natal*, third son of the late Dr W B Murray, of Tenbury, Worcestershire

THE CENTRAL MEDICAL WAR COMMITTEE LORD DERBY'S SCHEME

The Central Medical War Committee, which has worked out a system of recruiting officers for the R A M C, is at present completing a list of all medical men of *military age (that* is to say, all of 45 years or under) who have *not yet received* commissions It fully recognises the need for taking into consideration local and individual difficulties, and is in communication with the local Medical War *Committees* who are preparing lists of medical men of military age *for each area, classified according to the* scheme published in THE LANCET of Dec 11th, p 1321. As these local lists are completed a communication will be addressed to each medical practitioner of military age asking him to fill up a form, giving his name, age, *qualifications,* and *other* personal particulars, and another form authorising the Central Medical War Committee to forward to the War Office the application for a temporary commission in the Royal Army Medical Corps so soon as *in the opinion of that* Committee the time has arrived *for offering* his services The Committee on its part undertakes to give the applicant at least one month's notice On receipt of this form of application for a commission the Committee will at once send a certificate of enrolment, stating *that the application* has been received and is duly registered with the Committee This form of enrolment is equivalent to attestation under the Derby scheme, and applies only to men who are willing to give their whole time

The *applications for commissions* will *not* be sent into the War Office by the Central Medical War Committee until the circumstances in each case have been fully considered Thus there will be taken into account the individual's responsibilities with regard to *persons dependent upon him* and to partners, institutions, or public authorities, while in the general interests of the country the medical needs of each area will be thought of and precautions taken so that the proportion to population of medical men *remaining in civil* practice may be equalised throughout the country There are residential areas where the *proportion* of medical men in civil practice is very much *higher than in industrial districts*, and it is certain that *further* calls must be made upon *men practising* in such areas The Central Medical War Committee is aware that the conditions under which the public have been accustomed in time *of* peace to obtain the *attendance of medical men cannot* continue without modification

It is not possible to mention any number as the total of medical men who will be required by the army within a stated time, this must *depend* partly upon *the development of military operations,* and partly upon the amount of wastage among medical men already serving in the army The understanding is that when the Army Medical Department needs more medical *officers* it will state the number *required to the Central* Medical War Committee, that Committee will then inspect the whole list of enrolled men and will select those who, from the information in the possession of the Local Medical War Committees *and the general information* as to the whole country in the possession of the Central Medical War Committee, can be withdrawn *from civil* practice with least disadvantage to the public and to themselves

The scheme under *which doctors* are now invited *to enrol* with the Central Medical War Committee ensures that they will engage under the conditions which have prevailed since the beginning of the war—that is to say, the commission they promise to accept will be for a year, at the end of which time they will be able to review the position The Committee points out that if the opportunity is lost and compulsion has to be faced it is possible that the whole medical profession will be converted into a State service, when compulsion on the individual will not be limited in time, but he will be required to serve at least for the duration of the war

Measures taken in France for Prevention of Chilled Feet and Frost bite

Readers of the leading article in our issue of Dec. 11th, 1915, on the subject of trench foot will be interested in the following official summary of the measures which have been taken in France to prevent this condition —

1. Chilled feet and frost-bite are, it is stated, caused by (*a*) Prolonged standing in cold water or mud. (*b*) The continued wearing of wet socks, boots, and puttees

2. They are brought on much more rapidly when the blood circulation in the feet and legs is interfered with by the use of tight boots, tight puttees, or the wearing of anything calculated to cause constriction of the lower limbs.

3 They can therefore be prevented or diminished by (*a*) Improvements to trenches leading to dry standing and warmth. (*b*) By reducing the time spent in the trenches as far as the military situation permits (*c*) By regimental arrangements ensuring that, so far as is possible, men enter the trenches warmly clad in dry socks, boots, trousers, and puttees, and with the skin well rubbed with whale oil or anti frost-bite grease. (*d*) By provision of warm food in the trenches when possible. (*e*) By movement, when possible, so as to maintain blood circulation. (*f*) By the provision of warmth shelter hot food, and facilities for washing the feet and drying wet clothes for men leaving the trenches.

4 In order to minimise the prevalence of chilled feet and frost-bite the following instructions are to be carried out unremittingly and under the strictest supervision —(*a*) Before entering the trenches feet and legs will be washed and dried then well rubbed with whale oil or anti frost-bite grease and dry socks put on. It is of the utmost importance that whale oil or anti frost-bite grease should not merely be applied *but thoroughly rubbed in until the skin is dry* Unless this precaution is systematically carried out the oil and grease become in a great measure valueless (*b*) A second pair of dry socks will be carried by each man and, where possible, arrangements will be made for socks to be dried and reissued during each tour of duty in the trenches (*c*) While in the trenches boots and socks will be taken off from time to time, if circumstances permit, the feet dried well rubbed and dry socks put on (*d*) On no account will hot water be used nor the feet held near a fire (*e*) Where possible, hot food will be provided during tours of duty in the trenches (*f*) Where circumstances admit, long gum boots will be put on while the men's feet are dry before entering wet trenches, in order that men start their tour of duty with dry feet (*g*) When gum boots are worn it is well to support the socks by some form of fastening such as a safety pin, to prevent them from working down under the heel On no account will anything in the form of a garter be worn. (*h*) When conditions are favourable rest posts will be instituted in proximity to the trenches where men who show signs of suffering from exposure can be promptly attended to

5 Provision will be made for the washing and drying of feet in reserve billets for the exchanging of wet socks for dry ones and if possible the sending of the latter to the trenches and for drying and brushing clothes Steps will be taken to ensure that men make use of these arrangements

6 Long gum boots are being issued to the fullest extent of the supply available and every effort will be made to procure all that are necessary for men holding water logged trenches The distribution of these boots depends upon the necessity for their use and will therefore be made not according to numerical strength, but according to the nature of the trenches which have to be held

Proposal for a College of Nursing

We have received from the matron in chief of the Joint War Committee of the British Red Cross Society and the Order of St John of Jerusalem a letter signed by the Hon. Arthur Stanley, chairman of the committee, suggesting the foundation of a College of Nursing The proposal is the far reaching one of organising the teaching and examining of candidates for entrance to the nursing profession in the same way as the Conjoint Board has done this for the medical profession and the chartered institutes for other callings Promoters of the college are to be sought amongst the chairmen and governors of leading hospitals, physicians and surgeons who lecture to nurses, the principals of nurse training schools and of nursing associations, and other persons interested in the education of women If the proposals meet with general support it is believed that financial assistance can be secured to launch the college in a suitable building

The Loss of H M Cruiser "Natal."—The explosion on board the *Natal* in harbour on Thursday, Dec. 30th, 1915, led to the regrettable loss of some 300 lives, including those of Staff-Surgeon Alfred O Hooper, R N, and Surgeon Douglas W K Moody, R N, recorded in our casualty list It is a matter for congratulation that Fleet-Surgeon Ernest S Tuck was amongst the saved.

Vacancies for Medical Officers—Three medical officers are urgently required for the 2/1st Highland Mounted Brigade now sending drafts of officers and men overseas—one regimental medical officer for the 2/2nd Lovat Scouts, and two for the 2/1st Highland Mountain Brigade Field Ambulance. Full particulars of pay and duties from Captain Mowat, Officer Commanding 2/1st Highland Mounted Brigade Field Ambulance, R.A.M C 2, Mount-street, Diss, Norfolk.

Experiences in a German Military Hospital.—Dr Eloesser of San Francisco, has been working in a German military hospital for three months, and gives an account of his experiences in the *Journal of the American Medical Association* of Dec 4th, 1915 His views are very similar to those developed in our surgeons by the war Dum dum bullets may perhaps be used, but the ordinary bullet makes precisely similar wounds and the English bullet is perhaps the worst of all, the French the most humane Artillery wounds are the most horrible of the horrors of war, worse than any of the cruelties imagined by the torturers of old They are always infected and are becoming worse infected as the war goes on and the men's clothing becomes dirtier and the ground about the trenches more of a cemetery The prophylactic injection of antitetanic serum has extinguished tetanus All wounds require to be cleaned and disinfected at once, no surgeon would neglect this duty if he could see his cases two days later when inflammation has broken loose and extensive incisions are required to open up and expose to the air the infected tissues of the gas phlegmons Besides it is impossible to say when the infection is conquered It is so ready to break out again. The best splint is one well-fitting and windowed, made of plaster-of Paris but many surgeons called up for war have long forgotten how to apply that, besides, there is rarely time. Splints as usually applied are chiefly a balm to the surgeon's conscience There was no deficiency in the German hospitals in any direction, no stint of absorbent cotton or rubber goods "which one would imagine to be scant during the blockade." Great foresight is credited to the organisations which are training the crippled men to be again useful. They strive to educate each man in his own trade teaching the one-armed bricklayer mechanical drawing and architecture for example so that some of the crippled already earn larger wages than before they were wounded and their former knowledge is a foundation for that being imparted to them The number of prisoners to be fed in Germany has caused considerable difficulty In the first place it was difficult to find suitable staffs for the camps but special courses having been held last June for cooks and stewards all is now in order The Government has established a central depot for stores to diminish cost of purchases, and the diet contains

85 grm albumin, 40 grm fat, and 475 grm of carbohydrates, 2700 calories Prisoners employed get 10 per cent more, and those doing hard labour are paid for their work and can buy themselves extras The cost of the ration to the Government is 52 pfennigs (or 6½*d*) daily

THE WELSH GENERAL HOSPITAL —This hospital, to which we have already referred, is a general hospital of 1040 beds, the personnel of which is being raised by Wales for overseas service. The medical staff includes officers in charge of medical and surgical divisions, an ophthalmologist, pathologist, radiographer, and ear and throat specialist A dental surgeon with a medical qualification will also be accepted Appointments are for temporary commissions and for service with the hospital. Officers who already hold temporary commissions or Territorial commissions are not accepted, with this exception, that the officer in charge of the medical and surgical divisions, who should be consultants in their own branches may be transferred from Territorial units if they can be spared The hospital is under the command of Lieutenant-Colonel A W Sheen, R A M C (T F), and leaves probably some time in February next Forms of application for posts can be obtained from the honorary secretaries, Welsh Hospitals Offices, 47, Principality Buildings, Cardiff

WORK OF THE RED CROSS —Last week we noticed under this heading the joint work of the British Red Cross and the Order of St John of Jerusalem We now have before us the third interim report of the Red Cross work of the Indian branch of the St John Ambulance Association which took up the rôle of a Red Cross Society in India at the beginning of the war, and its remarkable achievements have called forth the highest praise from the highest authorities Some five years ago the total assets of the association in India amounted to only a few hundred rupees, while to-day it can boast of having collected the splendid sum of over three and a half lakhs, while it has dispatched Red Cross gifts and material to the value of no less than ten lakhs to the various theatres of war It has also raised 14 motor ambulances, it has sent a small fleet of motor ambulance boats up the Persian Gulf, it has assisted to equip military war hospitals in India, it has helped the sister Red Cross societies of all the Allies by gifts of material and money, besides establishing a hospital in India for the reception of severely wounded officers and men requiring electrical treatment This is not an exhaustive list of its activities, but it is sufficient to show the great value of its work The report, which is signed by the chairman of the executive committee, Surgeon General Sir *Charles Pardey Lukis*, I M S , is illustrated with pictures showing details of the work of the association

GERMANY'S PROHIBITION OF EXPORT OF MEDICAL PUBLICATIONS —A Swiss Correspondent writes "The *Journal de Genève* contrasts the present attitude of German doctors with that of German mechanical engineers—a comparison greatly in the favour of the latter Mechanical engineers are making great efforts to invent a really adequate artificial hand A prize of £2000 has been offered by the Association of German Engineers to the most successful inventor At a recent meeting of this very numerous association the president declared that he hoped any invention in this direction resulting from the labours of the members would benefit not only Germany and its allies but also their enemies These humane sentiments are in striking contrast with the spirit which has prompted the prohibition of the exportation of all medical publications This measure has been adopted in so rigorous a fashion that Swiss doctors can no longer obtain copies of books which have been published for them in Germany The idea underlying this prohibition is that the enemies of the Fatherland should not profit in the least degree from any progress that may be made in German surgery"

WELSH MEDICAL ORDERLIES —As the outcome of a conference of religious leaders in North Wales the War Office has given permission for the formation of a Royal Army Medical Corps unit consisting of 240 theological students, young clergymen, and ministers

KAISER'S CORFU PALACE AS SERBIAN HOSPITAL —It is stated that the British Government intends to take over the Achilleion, the Emperor William s Palace at Corfu as a hospital for wounded Serbians

Diploma in Public Health —Beatrice Garvie

CENTRAL MIDWIVES BOARD —A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Dec 16th, 1915 with Sir Francis H Champneys in the chair A letter addressed to the chairman from Mrs Gow, of Dean's Yard Westminster, urging the desirability of communicating with the London County Council asking that body not to delegate to the various borough councils its powers and duties under the Registration of Lying in Homes Act 1915, was considered. The Board deemed it necessary, in view of the power given to the London County Council by its General Powers Act, 1915, Part IV (Registration of Lying in Homes), to delegate its powers and duties to the various borough councils and the possibility of the County Council adopting such a course to reaffirm its resolution of July 22nd, 1915, which was as follows —

> That the Board strongly approves the view of the chairman expressed in his letter to Dr W H Hamer of July 16th 1915,

(i e., that the Act should be administered by the Council) A letter was considered from the county medical officer of health of Lancashire asking the opinion of the Board on a request made by one of the Lancashire non county boroughs that the borough health visitor should be allowed to call at houses in which a confinement has recently taken place and at which a certified midwife is in attendance with a view to supervising the midwife at work The Board directed that the county medical officer of health of Lancashire be informed that the Central Midwives Board is of opinion that, generally speaking, the inspector of midwives is the only person who ought to visit the house of a lying in patient during the attendance of the midwife, and that any visit paid to a lying in woman by any other person than the doctor or midwife must be made by the express permission of the patient A letter was considered from the clerk of the county council of Durham asking the opinion of the Board as to the signing of maternity benefit forms by a registered medical practitioner where the patient has been delivered by an uncertified woman The Board decided that the clerk of the county council of Durham be informed that in the opinion of the Board the case is one in which a representation should be made by the county council of Durham to the General Medical Council with a view to action being taken in the case and that he be asked whether the county council of Durham is willing to undertake such representation. A communication was received from the town clerk of Rotherham calling the attention of the Board to a case in which a registered medical practitioner had apparently been in the habit of signing maternity benefit forms in cases where the patient had been delivered on the previous day by an uncertified woman The Board decided that the town clerk of Rotherham be informed that in the opinion of the Board the case is one in which a representation should be made by the county borough of Rotherham to the General Medical Council with a view to action being taken in the case A letter was considered from the county medical officer of health of Gloucestershire asking the opinion of the Board as to the powers of a local supervising authority under Rule E 24 to make an inspection of the place of residence of a midwife when thought necessary The Board directed that the county medical officer of health of Gloucestershire be informed that under Rule E 24 the local supervising authority has authority to make an inspection of the midwife's residence to see if it is unsafe from a sanitary point of view for the confinements of women within it or for the confinements of others from the contamination of the midwife

Special meetings of the Board were held at Caxton House Westminster on Dec. 16th and 17th, 1915 with Sir Francis H Champneys in the chair A number of midwives were struck off the roll, the following charges amongst others having been brought forward The midwife being unable to take the pulse of her patients and being unable to make use of a clinical thermometer so as to comply with the requirements of Rule E 13, a patient suffering from an attack of faintness after the delivery and suffering from persistent headache and thirst and from serious symptoms of illness with a temperature of 102° F, the midwife did not at any time explain that the case was one in which the attendance of a registered medical practitioner was required, as prescribed by Rule E 19, she did not carry with her when attending patients the antiseptics required by Rule E 2, and did not keep her register of cases as required by Rule E 23 A child being stillborn and no registered medical practitioner having been in attendance at the time of birth, the midwife neglected to notify the local supervising authority thereof, as required by Rule E 21 (1) (c), medical aid having been sought in respect of the child she neglected to notify the local supervising authority thereof, as required by Rule E 21 (1) (a) The midwife neglecting to disinfect her hands and forearms at a confinement as required by Rule E 3, not being scrupulously clean in her person and house as required by Rule E 1, making false records of the temperature of patients The midwife did not before delivering the patient wash and swab her external parts in manner prescribed by Rule E 7, neglecting to cleanse the child's eyelids as soon as the head was born, as required by Rule E 15, and having administered a drug other than a simple aperient she neglected to note the occurrence in her register of cases as required by Rule E 18 A child suffering from inflammation of and discharge from, the eyes and continuing so to suffer on the date of the midwife's last visit, she did not explain that the case was one in which the attendance of a registered medical practitioner was required, as prescribed by Rule E 20 (5), she discontinued her attendance at a time when the condition of the child was not satisfactory—viz., when it was suffering from discharge from the eyes—and advised the mother of the child to take steps to prevent the condition of the child from becoming known to the officials of the local supervising authority A midwife not taking with her to a confinement a bag or basket for her appliances furnished with a removable lining which can be disinfected, as required by Rule E 2

TOXIC JAUNDICE AS A NOTIFIABLE DISEASE — Last week we published an account of a fatal case of "dope" poisoning associated with jaundice Dr W E Lee stated there that the composition of the dope was acetate of cellulose or celluloid dissolved in tetrachlorethane with amyl alcohol and benzene. The Home Secretary has now issued an Order making cases of toxic jaundice occurring in a factory or workshop—' that is, jaundice due to tetrachlorethane or nitro- or amido- derivatives of benzene or other poisonous substance —notifiable under the Factory and Workshops Act The Order came into force on Jan 1st, 1916

UNIVERSITY OF EDINBURGH.—During the year just brought to a close the total number of matriculated students (including 487 women—59 under last year's number) was 1853 being 676 fewer than the total for 1914 and 1408 fewer than the number for 1913 Of these, 807 (including 11 women) were enrolled in the Faculty of Medicine (a decrease of 218). Of the students of medicine 382 or over 47 per cent, belonged to Scotland, 122, or over 15 per cent, were from England and Wales, 30 from Ireland, 80 from India, 193 or nearly 24 per cent, from British Colonies and Dependencies, and 26 from foreign countries The number of women attending extra-academical lectures with a view to graduation in medicine in the University was 138 (an increase of 44 on the number for 1914) The University roll of war service—embracing members of the staff graduates, and students past and present—which a year ago contained about 1700 names, has now reached a total of nearly 4000 to which should be added about 400 who are members of the Officers Training Corps The University authorities have renewed with modifications various concessions made last year to students on service, and a number of scholarships &c. which would in ordinary course, have been tenable or open for competition this session have been suspended. The following medical degrees were conferred during 1915 Bachelor of Medicine and Bachelor of Surgery (M B, Ch.B), 158, Doctor of Medicine (M D) 21. The total annual value of the University fellowships bursaries and prizes now amounts to about £20 305 of which the Faculty of Medicine claims £5365 Early in the year the vacancy occasioned by the retirement of Professor John Wyllie was filled by the appointment to the

85 grm albumin, 40 grm fat, and 475 grm. of carbohydrates, 2700 calories Prisoners employed get 10 per cent more, and those doing hard labour are paid for their work and can buy themselves extras The cost of the ration to the Government is 52 pfennigs (or 6½*d*) daily

The Welsh General Hospital —This hospital, to which we have already referred, is a general hospital of 1040 beds, the personnel of which is being raised by Wales for *overseas service* The medical staff includes officers in charge of medical and surgical divisions, an ophthalmologist, pathologist, radiographer, and ear and throat specialist A dental surgeon with a medical qualification will also be accepted Appointments are for temporary commissions and for service with the hospital. Officers who already hold temporary commissions or Territorial commissions are not accepted, with this exception, that the officer in charge of the medical and surgical divisions who should be consultants in their own branches may be transferred from Territorial units if they can be spared The hospital is under the command of Lieutenant-Colonel A. W Sheen R A M C (T F), and leaves probably some time in February next Forms of application for posts can be obtained from the honorary secretaries Welsh Hospitals Offices, 47, Principality Buildings, Cardiff

Work of the Red Cross —Last week we noticed under this heading the joint work of the British Red Cross and the Order of St John of Jerusalem We now have before us the third interim report of the Red Cross work of the Indian branch of the St John Ambulance Association, which took up the rôle of a Red Cross Society in India at the beginning of the war, and its remarkable achievements have called forth the highest praise from the highest authorities Some five years ago the total assets of the association in India amounted to only a few hundred rupees, while to-day it can boast of having collected the splendid sum of over three and a half lakhs while it has dispatched Red Cross gifts and material to the value of no less than ten lakhs to the various theatres of war It has also raised 14 motor ambulances, it has sent a small fleet of motor ambulance boats up the Persian Gulf, it has assisted to equip military war hospitals in India, it has helped the sister Red Cross societies of all the Allies by gifts of material and money, besides establishing a hospital in India for the reception of severely wounded officers and men requiring electrical treatment This is not an exhaustive list of its activities but it is sufficient to show the great value of its work The report, which is signed by the chairman of the executive committee, Surgeon General Sir Charles Pardey Lukis I M S, is illustrated with pictures showing details of the work of the association

Germany's Prohibition of Export of Medical Publications —A Swiss Correspondent writes "The *Journal de Geneve* contrasts the present attitude of German doctors with that of German mechanical engineers—a comparison greatly in the favour of the latter Mechanical engineers are making great efforts to invent a really adequate artificial hand A prize of £2000 has been offered by the Association of German Engineers to the most successful inventor At a recent meeting of this very numerous association the president declared that he hoped any invention in this direction resulting from the labours of the members would benefit not only Germany and its allies but also their enemies These humane sentiments are in striking contrast with the spirit which has prompted the prohibition of the exportation of all medical publications This measure has been adopted in so rigorous a fashion that Swiss doctors can no longer obtain copies of books which have been published for them in Germany The idea underlying this prohibition is that the enemies of the Fatherland should not profit in the least degree from any progress that may be made in German surgery"

Central Midwives Board—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Dec 16th 1915, with Sir Francis H Champneys in the chair A letter addressed to the chairman from Mrs Gow, of Dean's Yard Westminster, urging the desirability of communicating with the London County Council asking that body not to delegate to the various borough councils its powers and duties under the Registration of Lying in Homes Act, 1915, was considered The Board deemed it necessary, in view of the power given to the London County Council by its General Powers Act, 1915, Part IV (Registration of Lying in Homes), to delegate its powers and duties to the various borough councils and the possibility of the County Council adopting such a course to reaffirm its resolution of July 22nd, 1915, which was as follows —

> That the Board strongly approves the view of the chairman expressed in his letter to Dr W H Hamer of July 16th 1915

(i e, that the Act should be administered by the Council) A letter was considered from the county medical officer of health of Lancashire asking the opinion of the Board on a request made by one of the Lancashire non county boroughs that the borough health visitor should be allowed to call at houses in which a confinement has recently taken place and at which a certified midwife is in attendance with a view to supervising the midwife at work The Board directed that the county medical officer of health of Lancashire be informed that the Central Midwives Board is of opinion that, generally speaking, the inspector of midwives is the only person who ought to visit the house of a lying in patient during the attendance of the midwife, and that any visit paid to a lying in woman by any other person than the doctor or midwife must be made by the express permission of the patient A letter was considered from the clerk of the county council of Durham asking the opinion of the Board as to the signing of maternity benefit forms by a registered medical practitioner where the patient has been delivered by an uncertified woman The Board decided that the clerk of the county council of Durham be informed that in the opinion of the Board the case is one in which a representation should be made by the county council of Durham to the General Medical Council with a view to action being taken in the case, and that he be asked whether the county council of Durham is willing to undertake such representation A communication was received from the town clerk of Rotherham calling the attention of the Board to a case in which a registered medical practitioner had apparently been in the habit of signing maternity benefit forms in cases where the patient had been delivered on the previous day by an uncertified woman The Board decided that the town clerk of Rotherham be informed that in the opinion of the Board the case is one in which a representation should be made by the county borough of Rotherham to the General Medical Council with a view to action being taken in the case A letter was considered from the county medical officer of health of Gloucestershire asking the opinion of the Board as to the powers of a local supervising authority under Rule E 24 to make an inspection of the place of residence of a midwife when thought necessary The Board directed that the county medical officer of health of Gloucestershire be informed that under Rule E 24 the local supervising authority has authority to make an inspection of the midwife s residence to see if it is unsafe from a sanitary point of view for the confinements of women within it, or for the confinements of others, from the contamination of the midwife

Special meetings of the Board were held at Caxton House Westminster on Dec 16th and 17th, 1915 with Sir Francis H Champneys in the chair A number of midwives were struck off the roll, the following charges, amongst others having been brought forward The midwife being unable to take the pulse of her patients and being unable to make use of a clinical thermometer so as to comply with the requirements of Rule E 13, a patient suffering from an attack of faintness after the delivery and suffering from persistent headache and thirst and from serious symptoms of illness with a temperature of 102° F, the midwife did not at any time explain that the case was one in which the attendance of a registered medical practitioner was required, as prescribed by Rule E 19, she did not carry with her when attending patients the antiseptics required by Rule E 2, and did not keep her register of cases as required by Rule E 23 A child being stillborn and no registered medical practitioner having been in attendance at the time of birth, the midwife neglected to notify the local supervising authority thereof, as required by Rule E 21 (1) (c), medical aid having been sought in respect of the child she neglected to notify the local supervising authority thereof as required by Rule E 21 (1) (a) The midwife neglecting to disinfect her hands and forearms at a confinement as required by Rule E 3, not being scrupulously clean in her person and house, as required by Rule E 1, making false records of the temperature of patients The midwife did not before delivering the patient wash and swab her external parts in manner prescribed by Rule E 7, neglecting to cleanse the child's eyelids as soon as the head was born, as required by Rule E 15, and having administered a drug other than a simple aperient, she neglected to note the occurrence in her register of cases, as required by Rule E 18 A child suffering from inflammation of, and discharge from, the eyes and continuing so to suffer on the date of the midwife's last visit, she did not explain that the case was one in which the attendance of a registered medical practitioner was required as prescribed by Rule E 20 (5), she discontinued her attendance at a time when the condition of the child was not satisfactory—viz, when it was suffering from discharge from the eyes—and advised the mother of the child to take steps to prevent the condition of the child from becoming known to the officials of the local supervising authority A midwife not taking with her to a confinement a bag or basket for her appliances furnished with a removable lining which can be disinfected, as required by Rule E 2

Toxic Jaundice as a Notifiable Disease—Last week we published an account of a fatal case of "dope' poisoning associated with jaundice Dr W E Lee stated there that the composition of the dope was acetate of cellulose or celluloid dissolved in tetrachlorethane, with amyl alcohol and benzene The Home Secretary has now issued an Order making cases of toxic jaundice occurring in a factory or workshop—"that is, jaundice due to tetrachlorethane or nitro- or amido- derivatives of benzene or other poisonous substance'—notifiable under the Factory and Workshops Act The Order came into force on Jan 1st, 1916

University of Edinburgh—During the year just brought to a close the total number of matriculated students (including 487 women—59 under last year's number) was 1853 being 676 fewer than the total for 1914, and 1408 fewer than the number for 1913 Of these, 807 (including 11 women) were enrolled in the Faculty of Medicine (a decrease of 218) Of the students of medicine, 382, or over 47 per cent, belonged to Scotland, 122, or over 15 per cent, were from England and Wales, 30 from Ireland, 80 from India, 193 or nearly 24 per cent, from British Colonies and Dependencies, and 26 from foreign countries The number of women attending extra academical lectures with a view to graduation in medicine in the University was 138 (an increase of 44 on the number for 1914) The University roll of war service—embracing members of the staff, graduates, and students, past and present—which a year ago contained about 1700 names, has now reached a total of nearly 4000, to which should be added about 400 who are members of the Officers Training Corps The University authorities have renewed with modifications various concessions made last year to students on service, and a number of scholarships &c., which would, in ordinary course have been tenable or open for competition this session, have been suspended The following medical degrees were conferred during 1915 Bachelor of Medicine and Bachelor of Surgery (M B, Ch B), 156, Doctor of Medicine (M D), 21. The total annual value of the University fellowships bursaries and prizes now amounts to about £20 305, of which the Faculty of Medicine claims £5365 Early in the year the vacancy occasioned by the retirement of Professor John Wyllie was filled by the appointment to the chair of Medicine of Professor Lovell Gulland Dr A M Drennan, formerly Lecturer in Practical Pathology, has been appointed Professor of Pathology in the University of Otago, New Zealand. Bequests of the James Cropper Scholarship Fund and the Waldie Griffith Scholarship Fund, for the medical education of women in Edinburgh, have been handed over to be administered by the University authorities The balance of the funds left over on the winding up of the Scottish Association for the Medical Education of Women has been given to the University Court for the foundation of an annual prize for a woman student qualifying in medicine

DR ANDREW DUNLOP —By the death of Dr Andrew Dunlop, at the age of 73, which occurred at St Heliers on Dec 30th last, the profession in Jersey has lost its doyen Dr Dunlop had of late been in failing health, and had recently suffered from heart trouble, but he had continued actively at work almost to the last, and the end—from cardiac failure—came rather suddenly Dr Dunlop's professional career in Jersey began in 1868, and he soon acquired an extensive general practice He held several honorary positions and appointments in connexion with the Jersey General Dispensary and other institutions, to which he devoted much time and attention He was one of the original founders of the Jersey Medical Society and for some years its president His medical contributions were accurate and painstaking an article on Rupture of the Heart appearing in 1866 (*Edinburgh Medical Journal*) may be specially mentioned In addition he was an enthusiastic geologist, and a writer on the subject, contributing frequently to the Société Jersiaise Dr Dunlop leaves a widow, a married daughter and two sons, having lost two sons in the South African War and three sons in the present war

HEALTH OF BELFAST —It is satisfactory to note that while in 1914 the death rate from all causes was 18 8 per 1000, the same rate, based on the returns for the 50 weeks ending Dec 18th 1915 is announced as 17 7 In 1914 there were 51 notifications of typhus, with 12 deaths, not a case of this zymotic has been reported in 1915 The estimated number of scarlet fever notifications for 1915 is 1992, against 2317 in 1914 and the notifications of diphtheria have fallen from 281 to 171 Cerebro spinal fever cases on the other hand have advanced from 14 in 1914 to 64 in 1915 The following tabular comparison is interesting —

Deaths from—	Total in 1914	Estimated total in 1915
Zymotic disease in general	1170	691
Typhoid fever	26	9
Measles	205	167
Scarlet fever	170	105
Whooping cough	205	155
Diphtheria	31	28
Diarrhœa	357	245
Phthisis	836	819
Chest diseases (including phthisis)	2466	2439
Death rate per 1000 of population from zymotic disease	2 7	1 7
Total infantile death rate per 1000	143	136

With reference to scarlet fever, the medical officer of health of Belfast believes that it is the delay in the diagnosis and notification of the first case until two or more of the family have become infected which causes the epidemic to continue He is a believer in the utility of hospital treatment for scarlet fever, and thinks that if cases were nursed at home the epidemic would be even more prevalent than it is

Mr John Howard, a well-known Brighton philanthropist figures among the recipients of New Year's honours conferred by the King A knighthood has been bestowed upon him His generosity has been boundless in all sorts of charitable causes, the most recent being his gift of £30 000 for establishing 24 cottage homes for trained nurses incapacitated through ill health or advancing years These homes as already recorded in THE LANCET are to be a memorial to Nurse Cavell Other benefactions have been the founding of the Howard Charity which provides pensions varying from 2*s* 6*d* to 8*s* a week to scores of deserving people and the building and endowment of the Howard Convalescent Home at a cost of £40,000 This home has been occupied by convalescent military and naval men ever since it was opened in September, 1914, Sir John Howard having placed it at the disposal of Lord Kitchener free of charge

THE SS "PERSIA"—The names of a medical man and a medical woman appear in the list of those on board the ill fated *Persia*, and unfortunately not among the rescued Dr William Everett, who was travelling as ship's surgeon, and Dr Elizabeth Stephens Impey, who was on her way to Lahore to take charge of the Lady Dufferin Hospital for Women

THE LATE DR C H FOX —Charles Henry Fox, M D St And, F R C P Edin, M R C S, died at his residence in Edinburgh on Christmas Day, in his seventy ninth year He received his medical education at St George's Hospital and Edinburgh University graduating M D of St Andrews in 1861, after having taken the M R C S in 1859 In 1900 he was admitted F R C P Edin Dr Fox was formerly physician to the Brislington House Private Lunatic Asylum, owned by himself and his half brother, Dr Bonville Fox Retiring in 1894, he spent the remainder of his life in Edinburgh

COMPLETION OF THE WESTERN INFIRMARY, GLASGOW —At a meeting held on Dec 23rd, 1915 in connexion with the Glasgow Western Infirmary, the new buildings were formally opened The chairman, Sir Matthew Arthur, referred to the handsome donation of £16,000 from the Davis trustees, which had enabled the management to complete the building plan of the admission department, which was the groundwork of the scheme, and to the generous gift of their friend and fellow manager, Mr William Robertson, who had already supplied the large ward of the new wing at a cost of £8000 and had now given £3500 for the equipment of the new operating theatre In the course of the proceedings the managers made an urgent appeal for financial support of the work of the institution, Colonel Roxburgh pointing out that the only alternative to public generosity was State aid

Mr C Welch, a Somerset landowner, who recently died leaving an estate valued at £24,155, bequeathed the residue of his property to the University of Oxford with certain conditions, failing which the property reverted to six London hospitals, one being St George's Hospital, but, said the testator, "no hospital is to be chosen by the trustees where vivisection is disallowed or discountenanced, anti vivisectionists being enemies of the human race"

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions and others possessing information suitable for this column are invited to forward to THE LANCET *Office directed to the Sub Editor not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication*

DAVIES A. L M R C S L R C P Lond has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Bala District of the county of Merioneth

FIELD F A. M D Lond has been appointed Deputy Medical Officer of Health of the Failsworth Urban District Council

FULTON JANE M M B B S R U I has been appointed Assistant Medical Officer at the Barming Heath Lunatic Asylum Maidstone

GRAVES T C M B B S Lond has been appointed Medical Superintendent of the Hereford County and City Asylum

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor

BIRKENHEAD BOROUGH HOSPITAL.—Junior House Surgeon Salary £160 per annum with board and laundry

BOLINGBROKE HOSPITAL, Wandsworth Common S W —House Surgeon Salary £200 per annum with board and residence

BRISTOL ROYAL INFIRMARY —House Physicians and House Surgeons Salary at rate of £120 per annum with board apartments and laundry

BURY INFIRMARY —Senior House Surgeon Salary £200 per annum with board residence and washing Also Junior House Surgeon. Salary £150 per annum with board residence and washing

WORCESTER COUNTY AND CITY ASYLUM Powick.—Junior Assistant Medical Officer Salary £250 per annum.

THE Chief Inspector of Factories Home Office London S W gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Baldock, in the county of Hertford

Births, Marriages, and Deaths.

BIRTHS

GRAY —On Dec. 26th 1915 at Alma House Exmouth the wife of Lieutenant Robin Gray R A.M.C of Stone House Chipping Sodbury of a daughter

NABARRO —On Dec 21 t 1915, at 117 Dartmouth road N W the wife (nee Florence Nora Webster) of David Nabarro M D Lond of a son

THWAITES —On Dec. 30th 1915 at St John s Park Blackheath, the wife of Captain H Thwaites R A.M.C., British Expeditionary Force, of a son

MARRIAGES

BOURKE—O CONNOR.—On Dec. 30th, 1915 at St Dominic s Church Haverstock hill N W Lieutenant Ulick J Bourke, R.A.M C to Agnes Mary daughter of the late J J O Connor and Mrs. O Connor

MASON—EASTMAN —On Jan 1st Arthur F Mason R.A.M C to Elsie Marion eldest daughter of Henry Eastman of Fernlea, Southampton

POWELL—COLE.—On Dec. 29th 1915, at Glencraig Church Craigavad, Ievan Herbert Powell B A. M B Dub B Ch T C.D., to Kathleen Harrietta Jacquetta elder daughter of Lieutenant T Willoughby Cole R A.M C (T)

DEATHS

DREW —On Dec 27th, 1915, at Montrose Battledown Cheltenham, peacefully after a long illness Joseph Drew M.B Lond M R.C S aged 89 years

DUNLOP —On Dec 30th 1915, at Belgrave House St. Hellier Jersey Andrew Dunlop M D Edin D P H Camb F G S aged 73 years

FAGGE.—On Jan 2nd at Effingham road, Lee Kent Frederick Thomas Fagge M R.C S., L.R C P Lond aged 76 years.

JOHNSON —On Nov 29th 1915 at Anzac, Major Frederick Miller Johnson A M C late of Melbourne Australia. M D Edin., C.M Lond grand nephew of the late Sir William Gull Bart.

MILLER.—On Dec 29th 1915 killed in action in France Albert Guy Miller Captain R A.M C aged 31 years.

ROBERTSON —On Jan 2nd Sir George Scott Robertson K C S I M.P

TANDY —On Dec 30th 1915 at the Red Cross Hospital Finsbury square Barre Latter Tandy L.R C S Irel L.R C P Edin. aged 70 years

THOMPSON —On Jan 1st in France Lieutenant W Frank Thompson R A.M C of the Leys School Cambridge and St Bartholomew s Hospital dearly loved elder son of Mr and Mrs W W Thompson of 3 The Avenue Brondesbury N W., aged 23 years

N B —A fee of [illegible] is charged for the Insertion of Notices of Births Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents

ELIMINATING THE TRAMP

IN these grim days of war much domestic legislation is put on one side, but the possibility of eliminating the tramp from the wayside does not seem to be out of the question if some figures just to hand can be taken as any criterion The success of the West Sussex vagrancy scheme is indeed remarkable It has now been in operation nine years and its three great principles are (1) Assistance for the genuine workman in search of employment (2) putting down the number of professional beggars and habitual vagrants and (3) the information of the general public, who are helped to see that there is no necessity for the indiscriminate giving of alms to wayfarers

In 1906, the year before the scheme was in operation, no fewer than 19,599 vagrants were relieved at the workhouses of eight unions in West Sussex in twelve months This huge figure appreciably declined when the vagrancy scheme operated and for the year 1915 was only 5817, or a decrease of 13,782 in nine years There has been a general decrease in the number of vagrants relieved throughout the United Kingdom but the West Sussex results have exceeded all expectations The cheapness of the system is not the least of its recommendations The cost of the food given to the vagrants relieved during the year just ended was only £33 16s 6d , a little more than usual owing to the Local Government Board adding to the dietary and to the increased cost of food. Even tramps of military age have been met with in West Sussex, and the attention of the Government authorities has been called to them in order that some steps may be taken to apply the National Registration to such men

TRACING PAPER

To the Editor of THE LANCET

SIR,—As medical men often use *tracing* paper for diagrams, charts, &c., they may like to know that in default of the usual tracing paper ordinary writing paper and scribbling paper may be quickly rendered transparent by pouring a small quantity of moderately viscid liquid paraffin B P on the paper and gently rubbing it in with the finger It is quickly absorbed and soon dries The drying may be accelerated by placing between blotting or other absorbent paper It bears ink and pencil marks well If it is desired to bring the transparent paper back to its pristine opaque condition it can be easily accomplished by placing it in a bottle with a little petrol and shaking it for two or three minutes The paraffin dries quicker than the castor oil which used to be employed for rendering paper negatives transparent for photographic reproduction

I am, Sir, yours faithfully,

Jan 4th, 1916 W F

"THE TEETHING FALLACY"

W M McD writes us at length on "The Influence of the Teething Fallacy as a Factor of Infantile Mortality and the Responsibility of the Medical Profession in the matter" He considers that the firm and unquestioned belief among the laity of all classes and among a great part of the medical profession that "baby must certainly be more or less ill whenever he is cutting a tooth" has led even among the best-intentioned mothers to an enormous amount of neglect of the first symptoms of illness in infants and that in this way thousands of infant lives are sacrificed to the fetish of teething In 19 years of general practice he has never come across any illness in an infant which could not satisfactorily be explained on other grounds than teething The subject is one of perennial interest and we deal with it in another column

BICENTENARY OF THE FIRM OF ALLEN AND HANBURYS LIMITED

ON Saturday Dec 18th 1915 the bicentenary of this firm was commemorated by the presentation of an oil portrait painting to Mr F J Hanbury, vice-chairman of the company and a cabinet of silver and a silver centre piece to Mr W R Dodd one of the directors In view of the serious times through which the nation is passing it was decided to make these presentations privately and the gathering was strictly confined to subscribers The celebration of the 200th anniversary of a great commercial business is a matter of national interest, and we offer our congratulations to this venerable and distinguished firm of British manufacturers

HEREDITY AS A FACTOR IN ALCOHOLIC DEGENERATION

THE Temperance Collegiate Association offers two prizes of 10 and 5 guineas respectively for the best essays on this subject sent in by Sept 30th next Conditions may be obtained from the Secretary of the Temperance Collegiate Association, Strathblane, Alexandra Park, Nottingham In this connexion the Science and Education Committee of the National Temperance League is willing to consider applications from university and hospital students in physics and medicine for financial assistance in carrying on research or in making investigations Applications should be addressed to the Secretary of the National Temperance League, Paternoster House, London, E C

HAZELL'S ANNUAL, 1916

THE war has no doubt seriously interfered with the compilation of annual books of reference but Hazell's appears betimes It is now in its thirty first year of issue, and under the editorship of Mr T A. Ingram, M A , LL D , maintains its reputation for giving the most recent and authoritative information concerning the British Empire, the nations of the world, and the important topics of the day The vast amount of information contained between the covers of this annual is indicated by the 10,000 entries of its excellent index Ample space is devoted to matters pertaining to the war, the communications from a naval officer forming a specially interesting chapter The new taxation and its effects receive considerable attention, and there are tables showing the rates of income tax payable on various incomes Messrs Hazell, Watson, and Viney, Limited, of 52, Long Acre, London, W C , are the publishers, and the price of the annual is 3s 6d

COCKENZIE FISHERMEN AND THE RED CROSS

ON the return of the Cockenzie fishing boats, after a successful fishing at Yarmouth, Colonel Caddell, V C , C B , made an appeal on behalf of the Red Cross to the fishermen who had been there As a result, £23 7s 6d have been subscribed by 56 of the fishermen of the nine crews engaged—a generous response considering that each boat has already subscribed between £3 and £4 to the Red Cross when at Yarmouth

TWO NURSING WAR DIARIES

MANY of the nurses at present in France send letters home to their friends, which are read with interest by their immediate circle The author of a "Diary of a Nursing Sister on the Western Front, 1914–1915" (William Blackwood and Sons Pp 300 Price 5s net) has been more ambitious in wishing to submit her daily jottings to a wider circle She discourses pleasantly enough of life on an ambulance train and with a field ambulance, and has an appropriate title for each section of her diary and a poem for each chapter Nurses who have more hum-drum duties at home may be glad to live the romance of war in these pages ——Miss Dorothy Cator writes more seriously of what she has learned "In a French Military Hospital" (Longmans, Green, and Co Pp 99 Price 2s 6d net), and the reader should be warned that the author has been "disappointed and disillusioned at every turn" She tells us that the French attitude to truth is, of course, different from the English one, and that any lie which helps to get through life gracefully is more than permissible if only it is told well enough not to be found out, that Frenchmen have much to learn from us in the way they treat their women, and so forth With a more sympathetic eye the author would have seen more, and more truly

BURBERRYS' SALE

Messrs Burberrys, of the Haymarket London, are holding their annual sale during the month of January, when in accordance with their custom, they will sell at half the usual prices all the stock remaining on their hands from the previous year The name of Burberrys, especially for weather proof clothes is well known amongst medical men, and some of our readers may be glad to replace a garment at a reduced cost Messrs Burberrys will send a catalogue on application

Recruit —1 Any previous overcrowding was local There were many localities undermanned 2 Many practitioners have been set free for the reasons given by our correspondent and to ascertain the number of men still available is one of the tasks now being worked at by the Central Medical War Committee 3 We think our correspondent might have received some credit for his previous experience

I P —We have had a favourable account of the institution

COMMUNICATIONS not noticed in our present issue will receive attention in our next

Medical Diary for the ensuing Week

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. *It is urgently necessary that attention should* be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE *AUTHOR AND IF POSSIBLE OF THE ARTICLE,* SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed 'To the Manager*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title-page to Vol. II. of 1915 were given in THE LANCET of Dec 25th, 1915

VOLUMES AND CASES

VOLUMES for the second half of the year 1915 will be ready shortly Bound in cloth, gilt lettered, price 16*s*, carriage extra.

Cases for binding the half-year s numbers are now ready Cloth gilt lettered, price 2*s*, by post 2*s* 4*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

ALTERATION OF INLAND SUBSCRIPTION RATES

OWING to the alteration in the Inland Newspaper Postal rate, the postage on each copy of THE LANCET will in future be 1*d*, and sometimes 1½*d*

The revised Inland Subscription rates are —

One Year	£1	3	3
Six Months	0	13	8
Three Months	0	7	0

The rates for the Colonies and Abroad (thin paper edition) will be as usual —

One Year	£1	5	0
Six Months	0	14	0
Three Months	0	7	0

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD THE LANCET Offices, 423, Strand, London W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

NEWSPAPERS FOR NEUTRAL COUNTRIES

THE Secretary of the War Office has issued the following order —

> The public are informed that on and after Saturday, November 6th, newspapers, magazines, books, and other printed publications (other than trade circulars) will not be sent forward to neutral European countries unless posted direct from the office of publishers or newsagents who have obtained permission from the War Office for this purpose Persons desiring to send newspapers &c to neutral European countries should, therefore give their orders for execution to publishers or newsagents who have obtained such permission

The Publisher of THE LANCET has obtained the required permission of the War Office and he will forward copies direct from the Office to any neutral country on receipt of instructions

Investigations
ON
CLINICAL THERMOMETRY
CONTINUOUS AND QUASI-CONTINUOUS TEMPERATURE RECORDS IN MAN AND ANIMALS IN HEALTH AND DISEASE

By G SIMS WOODHEAD M A, M D LL D
PROFESSOR OF PATHOLOGY CAMBRIDGE
AND
P C VARRIER-JONES, M A M R C S L R C P LOND
FOUNDATION SCHOLAR, ST JOHN'S COLLEGE, CAMBRIDGE
(From the Pathological Department, University of Cambridge)

PART I —THE CLINICAL THERMOMETER

In these days of routine temperature taking and recording it is difficult to realise that "Clinical Thermometry" was introduced no longer than 60, nay even 50, years ago Isolated and intermittent observations on the variations of the temperature of the human body in the course of disease had been made by thoughtful and scientific physicians especially those of the Edinburgh School—G Martine[1] G Cleghorn[2] J Currie[3] A. Arnott,[4] and others but no systematic clinical thermometry was attempted by the medical profession until Wunderlich's classical work was published, a work that could not have appeared had not Lord Kelvin in 1849 established his "Absolute Scale of Temperature" From 1857 to 1865 Wunderlich[5] taught with wonderful grasp and determination the value of the clinical thermometer, and with such success that a new era opened in medicine and surgery

Since that date the clinical thermometer has proved of such assistance to the physician and surgeon in diagnosis, treatment, and prognosis that several efforts, some successful, others less so, have from time to time been made to obtain not isolated but continuous records of temperature in health and disease Determining to supplement these efforts and to continue the investigations, we have for some time past been giving considerable attention to a study of the best method of obtaining, over prolonged periods continuous records of the temperature not only of human patients but of the lower animals The results of these investigations we now propose to give, first because they may be of interest to others, and, secondly, in order that those who become interested may take up the work, and, should they find it sufficiently productive, continue along the lines of our investigations Before doing this, however, we should like to give a short sketch, laying especial stress on British work of the advance of clinical thermometry

THE EARLY HISTORY OF CLINICAL THERMOMETRY

Hippocrates (460–370 B C) was well acquainted with the fact that during certain phases of disease the temperature of a patient may vary greatly, but it was not until a couple of thousand years had elapsed that the matter was deemed worthy of consideration by his successors

Sanctorius of Padua in his Commentary on the 1st book of the Canon of Avicenna (Venice, 1625) describes a thermometric apparatus, and though this is not quite clear from the text, assumes it as his own invention and manufacture, and to him certainly must be ascribed the idea of measuring degrees of heat by noting the expansion of matter as it is heated. He claims that with this apparatus he could determine the variations of temperature of the human body during the course of certain fevers † He was, however, so far ahead of his time that his work seems to have attracted little or no attention, and it was left to Boerhaave[6] a hundred years later, to maintain that "external febrile heat is recognised by the thermometer," and for van Swieten,[7] one of Boerhaave's pupils, to point out, in 1745, that the estimation of temperature by the hand is uncertain though he and his colleague, de Haen,[8] undoubtedly extended the practical application of thermometry in the study of disease

The method of using the thermometer adopted by the latter appears to have been somewhat crude and unsatisfactory, as he recounts that although he always kept the instrument (not a maximum thermometer) *in situ* for 7½ minutes, when he took a reading *he added one or two degrees Fahrenheit to*

---

* [illegible] In De Sta[illegible] [illegible] In Ga[illegible] [illegible] 321

† Martine writes (Essays [illegible] p 177) "It is not our business at present to determine to whom we owe that noble and useful discovery whether to Sanctorio to Galileo to Father Paul or to Drebbel for I find it ascribed to all these by their respective favourers and admirers. [In a footnote he adds The invention is given to Drebbel by his countrymen Boerhaave (Chem I., 152, 156) and Musschenbroek (Tent. Exp. Acad. Cim Add. p 8 Ess de Phys. § 945) Fulgenzio (Life of Father Paul p.m. 156) ascribes it to his master Father Paul Sarpi, that great oracle of the republic of Venice. But there was an humour prevailed in those days of fathering almost all the curious discoveries of the age on that great statesman and virtuoso Vincenzio Viviani (Vit. de l'Galil. p. 67 See too Oper di Galil. Pref. p 47) speaks of Galileo as the inventor of thermometers But we know how much and how fondly he adored the memory of his great master (See Hist Acad. des Scien 1705, pp 159 175 176 193) Still, all these are posthumous claims and they too imputed by others But Sanctorio himself (Com. in Galen. Art. Med. pp. 736, 842, Com. in Avicen Can. Fen. I pp 22, 78, 219) expressly assumes the invention in question And Borelli (de Mot Animal II Prop 175) and Malpighi (Oper Posth. p 30) ascribe it to him without reserve And these Florentine academicians are not to be suspected of partiality in favour of one of the Patavinian School]

At first as is the fate of all other inventions thermometers were but rude and imperfect machines, and not easily to be applied to so many purposes as came afterwards to be in use They were very clumsy and as the various degrees of heat were pointed by the different contraction or expansion of air they came afterwards to be found uncertain and sometimes to be deceiving measures of heat as the bulk of air was affected not only by the difference of heat but likewise by the difference of weight of the atmosphere."

Drebbel (1572–163[illegible]) is regarded as the inventor of the air thermometer Galileo (15[illegible]–1642) of the spirit thermometer (the Florentine thermometer) and Reaumur (O'e Römer) (15[illegible]–1710) of the mercurial thermometer (Jnl. Amer Med. Ass 1912, p 1473)

Sir Isaac Newton used linseed (lintseed) oil—"A homogeneous fluid enough and capable of a considerable rarefaction and not having been observed to freeze even in very great colds and able to bear a great heat without boiling" Martine from whose work the above is a quotation also says (p 196) "The great Sir Isaac Newton thought the settling the degrees of Heat and Cold well worth his notice and as he carried everything he meddled with beyond what anybody had done before him and generally with a greater than ordinary exactness and precision so he laid down a method of adjusting thermometers in a more definite way than had been done hitherto" This linseed oil was placed in a glass tube

Wilks (Brit. Med Jour., Oct. 2[illegible]th 19[illegible] p 121[illegible]) gives an interesting account of a scale described in a paper attributed to Sir Isaac Newton but definitely stated to be by him by Martine (op. cit., p 195) ("Scala graduum caloris" Phil. Trans., London 1701, vol xx p 824, April, 1701) in which the temperature of the human body is calculated as coming at a definite point between the temperature of thawing snow and the heat of water boiling strongly "Supposing the bulb when immersed in thawing snow to contain 10,000 parts, he found the oil expanded by the heat of the human body so as to take up 1 3[illegible]th more space or 10,256 such parts and by the heat of water boiling strongly 10,725 and by the heat of melting tin 11,516 beyond which he did not carry his Oil Thermometer So that reckoning the freezing point as a common limit between heat and cold, he began his scale here making it gr 0 and the heat of the human body he made gr 12 and consequently the heat of boiling water was expressed by gr 34 $= \frac{725 \times 12}{256}$ and melting tin by gr 71" (Martine p 1[illegible])

Fahrenheit assumed that the temperature of the human body his fixed starting point, from which he worked upwards and downwards [illegible] He took the temperature of a mixture of ice and salt as his zero point and counting the body temperature 12 he found that the freezing point of water on his scale was 8 and that boiling point of water 53 In order to lengthen his scale he multiplied all the above figures by 4 and obtained the figures 0, 32, 9[illegible] and 212. W[illegible] who quotes from the Encyclo[illegible] [illegible] says that he wishes [illegible] and that he does [illegible] [illegible] the thought

Investigations
of
CLINICAL THERMOMETRY

CONTINUOUS AND QUASI-CONTINUOUS TEMPERATURE RECORDS IN MAN AND ANIMALS IN HEALTH AND DISEASE

By G SIMS WOODHEAD, M.A, M D, LL D,
PROFESSOR OF PATHOLOGY CAMBRIDGE

AND

P C VARRIER-JONES, M.A M R C S
L R C P Lond
FOUNDATION SCHOLAR, ST JOHN'S COLLEGE, CAMBRIDGE.
(From the Pathological Department, University of Cambridge)

PART I —THE CLINICAL THERMOMETER

In these days of routine temperature taking and recording it is difficult to realise that "Clinical Thermometry' was introduced no longer than 60, nay even 50, years ago Isolated and intermittent observations on the variations of the temperature of the human body in the course of disease had been made by thoughtful and scientific physicians especially those of the Edinburgh School—G Martine[1] G Cleghorn[2] J Currie[3] A. Arnott,[4] and others, but no systematic clinical thermometry was attempted by the medical profession until Wunderlich's classical work was published, a work that could not have appeared had not Lord Kelvin in 1849 established his "Absolute Scale of Temperature' From 1857 to 1865 Wunderlich[5] taught with wonderful grasp and determination the value of the clinical thermometer, and with such success that a new era opened in medicine and surgery

Since that date the clinical thermometer has proved of such assistance to the physician and surgeon in diagnosis, treatment, and prognosis that several efforts, some successful, others less so have from time to time been made to obtain not isolated but continuous records of temperature in health and disease Determining to supplement these efforts and to continue the investigations, we have for some time past been giving considerable attention to a study of the best method of obtaining over prolonged periods continuous records of the temperature not only of human patients but of the lower animals The results of these investigations we now propose to give, first because they may be of interest to others, and, secondly, in order that those who become interested may take up the work and, should they find it sufficiently productive continue along the lines of our investigations Before doing this, however, we should like to give a short sketch, laying especial stress on British work, of the advance of clinical thermometry

The Early History of Clinical Thermometry

Hippocrates (460–370 B C) was well acquainted with the fact that during certain phases of disease the temperature of a patient may vary greatly, but it was not until a couple of thousand years had elapsed that the matter was deemed worthy of consideration by his successors

Sanctorius of Padua,[6] in his Commentary on the first book of the Canon of Avicenna (Venice, 1625) describes a thermometric apparatus, and though this is not quite clear from the text, assumes it as his own invention and manufacture, and to him certainly must be ascribed the idea of measuring degrees of heat by noting the expansion of matter as it is heated. He claims that with this apparatus he could determine the variations of temperature of the human body during the course of certain fevers † He was, however, so far ahead of his time that his work seems to have attracted little or no attention, and it was left to Boerhaave[7] a hundred years later, to maintain that "external febrile heat is recognised by the thermometer,' and for van Swieten,[8] one of Boerhaave's pupils, to point out, in 1745, that the estimation of temperature by the hand is uncertain though he and his colleague, de Haen,[9] undoubtedly extended the practical application of thermometry in the study of disease

The method of using the thermometer adopted by the latter appears to have been somewhat crude and unsatisfactory, as he recounts that although he always kept the instrument (not a maximum thermometer) *in situ* for 7½ minutes when he took a reading *he added one or two degrees Fahrenheit to*

[illegible] De Sa[illegible] [illegible] Ga[illegible] No 4221.

† Martine writes (Essays, 17[illegible] p 177) "It is not our business at present to determine to whom we owe that noble and useful discovery whether to Sanctorio to Galileo to Father Paul or to Drebbel for I find it ascribed to all these by their respective favourers and admirers [In a footnote he adds "The invention is given to Drebbel by his countrymen Boerhaave (Chem I 152, 156) and Musschenbroek (Tent Exp Acad. Cim Add. p 8, Ess de Phys § 9[illegible]). Fulgenzio (Life of Father Paul p.m. 158) ascribes it to his master Father Paul Sarpi, that great oracle of the republic of Venice But there was an humour prevailed in those days of fathering almost all the curious discoveries of the age on that great statesman and virtuoso Vincenzio Viviani (Vit. de l Galil. p. 67 See too Oper di Galil. Pref. p [illegible]7) speaks of Galileo as the inventor of thermometers But we know how much and how fondly he adored the memory of his great master (See Hist Acad. des Scien 1708, pp 1[illegible] 175 1[illegible]) Still all these are posthumous claims and they too imputed by others. But Sanctorio himself (Com. in Galen. Art. Med. pp. 736, 8[illegible]2 Com. in Avicen Can. Fen. I pp 22, 7[illegible], 219) expressly assumes the invention in question. And Borelli (de Mot. Animal II Prop 175) and Malpighi (Oper Posth p 30) ascribe it to him without reserve And these Florentine academicians are not to be suspected of partiality in favour of one of the Patavinian School."]

At first as is the fate of all other inventions, thermometers were but rude and imperfect machines and not easily to be applied to so many purposes as came afterwards to be in use They were very clumsy and as the various degrees of heat were pointed by the different contraction or expansion of air they came afterwards to be found uncertain and sometimes to be deceiving measures of heat as the bulk of air was affected not only by the difference of heat, but likewise by the difference of weight of the atmosphere."

Drebbel (1572-163[illegible]) is regarded as the inventor of the air thermometer Galileo (15[illegible]–16[illegible]2) of the spirit thermometer (the Florentine thermometer) and Réaumur (Ole Römer) (16[illegible]–1710) of the mercurial thermometer (Jnl. Amer Med. Ass. 1912, p 1[illegible]75)

Sir Isaac Newton used linseed (lintseed) oil—"A homogeneous fluid enough and capable of a considerable rarefaction and not having been observed to freeze even in very great colds and able to bear a great heat without boiling" Martine from whose work the above is a quotation, also says (p. 195) "The great Sir Isaac Newton thought the settling the degrees of Heat and Cold well worth his notice and as he carried everything he meddled with beyond what anybody had done before him and generally with a greater than ordinary exactness and precision so he laid down a method of adjusting thermometers in a more definite way than had been done hitherto" This linseed oil was placed in a glass tube.

Wilks (Brit. Med. Jour., Oct. 2[illegible]th 190[illegible] p 1212) gives an interesting account of a scale described in a paper attributed to Sir Isaac Newton but definitely stated to be by him by Martine (op. cit., p 195) ("Scala graduum caloris" Phil. Trans., London 1701 vol. xx., p 82 April 1701) in which the temperature of the human body is calculated as coming at a definite point between the temperature of thawing snow and the heat of water boiling strongly "Supposing the bulb when immersed in [illegible] snow to contain 10000 parts, he found the oil expanded by the heat of the human body, so as to take up 1[illegible]th more space or 10 256 such parts and by the heat of water [illegible] strongly 10725 and by the heat of [illegible] 11,5[illegible] beyond which he did not carry his Oil Thermometer So that reckoning the *freezing* point as a common limit between heat and cold, he began his scale here making it gr 0 and the heat of the [illegible] he made gr 12 and consequently the heat of [illegible] was expressed by gr 34 = $\frac{725 \times 12}{256}$ and [illegible] by gr 71" (Martine p 195)

Fahrenheit also made the temperature of the human body his fixed starting point, from which he worked upwards and downwards but he took the temperature of a mixture of ice and salt as his zero point and counting the body temperature 12 he found that the freezing point of water on his scale was 8 and the boiling point of water [illegible] In order to lengthen his scale he multiplied all the above figures by [illegible] and obtained the figures 0, 32, [illegible] and [illegible]. Wilks who quotes from the Encyclopaedia Britannica, says that he wishes to accept this and that he does not think that [illegible] to the [illegible] *the temperatures registered "because he found the mercury would rise as much if left longer"* De Haen, however, appreciated the importance of a normal standard, and made a number of observations on the temperature of healthy people at various ages, comparing his results with those he obtained in the sick room The morning remission and evening exacerbation of temperature in fevers were well known to him He used variations of temperature as aids to the control and direction of his therapeutics, and regarded the return of the temperature to normal as a proof of convalescence

A few years earlier, however, George Martine,[1] trained partly in Edinburgh University but a graduate of the University of Leyden, dating from St Andrews, August, 1738, had published the first accurate observations on the temperature of healthy man and animals His "Essays and Observations" are considered by Garrison[10] to be the only scientific treatment of the subject that we have, earlier than that given to it by Wunderlich, and he it was who appears to have stimulated Haller's follower, Marcard[11] to the observations in his dissertation which appeared in 1741, and to have encouraged Pickel[12] to record his experiments on the influence of bathing in rivers on the body temperature which were published in 1778

Position in Latter Half of Eighteenth Century

Cleghorn[2] and Lining (a description of the American Yellow Fever, letter to Whyte published in Edinburgh, May 7th, 1754) both refer to their observations of the corporal temperature, the former in pneumonia as early as 1745, when he describes "an intense heat over the whole body which raises the mercury in the thermometer to the 103rd or 104th degree, and in pleurisy, in which he states that the external heat of the body was in several very moderate, in some less than natural, but for the most part it was so intense as to raise the mercury in Fahrenheit's thermometer to the 102nd degree, and often in the afternoon to the 104th (p 244), the latter in yellow fever before December, 1753

In 1775 Blagden,[13] writing in the Philosophical Transactions, published a series of observations and experiments as the outcome of which he was able to insist upon the remarkable power of accommodation for changes of temperature possessed by warm blooded animals, and the maintenance of normal temperature in healthy men in rooms heated to the boiling point of water These experiments by Blagden led John Hunter[14] to publish his experiments, begun in 1766, by which he proved that animals are able to resist external cold because they produce in themselves heat enough to counterbalance all loss Hunter also noted in his "Treatise on the Blood, &c," in 1793 (p 338 of reprinted works) that local inflammation produces a rise in temperature at the inflamed spot, and he held most tenaciously that body heat is not produced by the circulation of the blood

> It is very evident [he says] that warmth depends on a different principle which is intimately connected with life itself and is a power which maintains and regulates the machine independent alike of the circulation, the will and of sensation

In the Philosophical Transactions for 1778 he writes —

> In the course of a variety of experiments on animals and vegetables I have frequently observed that the result of experiments in the one has explained the œconomy of the other and pointed out some principle common to both, I have therefore, collected some experiments which relate to the heat and cold of those substances Having found variations in the degree of heat and cold in the same experiment, for which I could not account, I suspected that this might arise from some imperfections in the construction of the thermometer I mentioned to Mr Ramsden my objections to the common construction of that instrument, and my idea of one more perfect in its nature, and better adapted to the experiments in which I was engaged He accordingly made me some very small thermometers, six or seven inches long not above two-twelfths of an inch thick in the stem, having the external diameter of the ball very little larger than that of the stem, on which was marked the freezing point The stem was embraced by a small ivory scale, so as to slide upon it easily and retain any position. Upon the hollow surface of this scale were marked the degrees which were seen through the stem. By these means the size of the thermometer was very much reduced, and it could be applied to soft bodies with much more ease and certainty, and in many cases in which the former ones could not be conveniently applied. I therefore repeated with it such of my former experiments as were not originally satisfactory, and found the degrees of heat very different, not only from what I generally imagined but also from what I had found by my former experiments with thermometers of the common construction

Lavoisier and Laplace[15] (the celebrated astronomer), 1780, investigating the cause of animal heat, ascribed it to the chemical combination of oxygen with hydrogen and carbon in respiration.

In 1797 James Currie,[8] of Liverpool, trained in Edinburgh but a graduate in medicine of Glasgow University, in applying water, both cold and warm, as a remedy for fever and other diseases, made great use of thermometric methods, upon which he depended greatly for indications as to the results of his treatment He tested the action of warm and cold baths, of digitalis, opium and alcohol, and of restricted diet in the production of alterations of temperature[‡] So great was the value placed by him upon temperature observation as an aid to diagnosis and treatment that he was looked askance at by the rest of the profession, and this part of his work was commented on by his German translator as affording a glaring instance of the miserably backward state of medicine in England (Wunderlich[5]) As indicating the value of contemporary criticism, Weir Mitchell[16] finds "absolute genius" in Currie's book (Garrison,[10] p 288)

Clinical Thermometry in Early Part of Nineteenth Century

Elisha North[17] who recommended the use of the thermometer in spotted fever, Sir Benjamin Brodie,[18] who observed, in a case in which there was laceration of the lower part of the cervical portion of the spinal cord, that when the ball of the thermometer was placed between the scrotum and the thigh the quicksilver rose to 111° F, and that immediately after death the temperature was determined in the same manner and was found to be still the same, Dalton,[19] John Davy,[20] both of these latter opposing Brodie on his theory as to the influence of the nervous system on animal heat, Gentil,[21] Thomson,[22] and Sir Everard Home,[23] who, we are not astonished to find, obtained records of some remarkably high temperatures, 118° F in one instance, all studied clinical thermometry *at the* beginning of the nineteenth century, but it was left, in the early years of the renaissance of science, 1835 and onwards, to Becquerel and Breschet[24] and their followers to bring forward series of observations made with exceedingly sensitive thermometric apparatus on the variations of temperature in different parts of the bodies of animals It was noted that inflamed parts had a higher temperature than that recorded for the rest of the body No attempt was made, however, to register these temperatures or to obtain any continuous or automatic records In 1836 Berger[25] made a study of the temperatures of various species of animals

---

[‡] Currie writes in vol I p 11: "The pulse varied from 130 strokes in the minute to 160 the heat rose in one case to 10[illegible]° of Fahrenheit but was in general from 101° to 103° towards the latter stage [illegible] the disease it was scarcely above the temperature of health [illegible] p 24 On the 18th at noon his pulse was 95 and soft; his [illegible] moist but a little above the natural heat His tongue was a [illegible] furred and his head ached he also complained of thirst the [illegible] at the axilla was 100° " &c And so throughout a number of his [illegible] of cases In vol II p 65 Dr Gregory writing to Currie [illegible] cases of scarlatina said "I did not take time to measure the [illegible] of his skin by the thermometer but I think it must have been at least 104° of Fahrenheit "

[§] Dr John Davy in "Physiological Researches" gives the fluctuations of temperature within the limits of health in tempera[illegible] (England) as highest in the morning between 7 and 8 [illegible] in the afternoon from 3 to [illegible] and 97·[illegible] at midnight He also [illegible] that it fluctuates till nightfall and is lowest about midnight [illegible] average difference of about 0 82°

The use of the thermometer in medical practice was, however, still regarded with suspicion, though individuals, Bouillaud,[26] Donne,[27] Piorry,[28] Wistinghausen,[29] Friedrich Hermann and D Nasse,[30] in addition to those already mentioned, claimed the thermometer as an instrument to be used in connexion with clinical investigation and treatment During the whole of the first four decades of the nineteenth century, however, the observations made on the temperature of the human body under varying conditions were but scanty, and as Hermann Nasse, in 1839,[31] puts it "For some years past the science of thermometry has been more neglected than formerly and indeed, remains almost *in statu quo* (quoted by Wunderlich)

In the *Medical and Physical Journal* (London, 1800, vol iii, p 304) a short descriptive notice is given of a portable thermometer (price 18s, provided by Messrs. Allen and Howard, chemists, in Plough-court, Lombard street, E C) designed to ascertain the heat of the human body The instrument, enclosed in a *cylindrical case, was about 5 inches* long and ¼ inch in diameter The scale (about 80° to 112°) was attached to the tube This instrument was so sensitive that the temperature was indicated in less than 10 seconds and might be read to a quarter of a degree

In its early history clinical thermometry was very closely linked up with hydropathy Dr Henry Willson[1] draws attention to an article in a "Report of the Society for Bettering the Condition of the Poor 1808 This article, entitled "Cases of Typhus Fever in which the Affusion of Cold Water has been Applied in the London House of Recovery, is by Dr W P Dimsdale, and contains interesting records of thermometry in connexion with this fever—'a thermometer placed under the tongue arose to 104°'

Dr Lloyd Jones[2] unearthed a most interesting note from 'Notes on a Diary kept *chiefly* in Southern India, 1881–6 by the Right Hon Sir Mountstuart E Grant Duff G C S I (vol ii p 208), in which a communication from Dr Birdie is quoted to the following effect —

> I also send a copy of the Report of the Committee on the Epidemic Fever in the Southern Provinces which prevailed 1809 11 Your Excellency will be pleased to notice at the top of p 52 [of the report] that the Committee used the thermometer as a clinical instrument long before its use as such was revived in Europe (*sic*) Curious to say that lunatic Tippu Sultan has some inkling of the use of the thermometer in disease as according to Wilks he wrote and asked Cossigny the Governor of Pondicherry, for an instrument of this kind which when the sick man places his hand on it the ascent of the quicksilver will mark the height of the disease

It is interesting to note that Archibald Arnott, an Edinburgh graduate (1815), Surgeon 20th Regiment, who was probably acquainted with Currie's treatise first published in 1797, makes the following *observation* whilst in attendance on Napoleon at St Helena.[32] On April 1st, 1821, *Arnott* first visited Napoleon and "as a result of the examination he could discover no tension or hardness of the abdomen, the pulse was tranquil and the heat moderate"[33] On April 3rd "he passed a tolerably tranquil night and slept a good deal, his pulse was 76, heat 96, skin more moist than natural, &c"[*]

PROGRESS IN MEDICAL THERMOMETRY FROM 1840

From the year 1840 a distinct advance in medical thermometry may be dated, and facts relating to temperature both in health and disease now began to accumulate and to be considered not as isolated observations but as having real clinical significance In this year Arnold[34] gives a very complete account of his investigations in thermometry in health and *disease in* his "Practical Treatise on Bilious Remittent Fever"

> "Preliminary experiments on the temperature of the system were instituted for the purpose of ascertaining the exact temperature of every class of residents in the island in a state of health, and under the various circumstances which are mentioned" (preface) To ascertain the normal temperature the experiments were made "upon every denomination of subject at different periods of the year, at different times of the day and under a great variety *of circumstances" and the author found that* '*the mean of* the whole series comprising 107 subjects of all denominations ages and sexes is 98 19 3/12th, which may be considered a correct estimate of the temperature of the system in health and as enjoyed in a climate like Jamaica" He took the temperature under the tongue and in the axilla, and notes 'there are generally one or two degrees of heat between the experiments under the tongue and in the axilla which was always found the lowest'
>
> *He then discusses the importance of temperature in the* febrile diseases 'for I have considered this symptom to be one of the most formidable with which we have to combat in the treatment of the bilious remittent fever, no matter where we may meet it, believing as I do that the system when labouring under this disease must inevitably give way to the cause which produces even a few degrees of thermal exaltation beyond 105° of Fahrenheit s scale and that all our remedies will have little effect if we find it 110° during the first or second stages I believe there is no study more calculated to improve the healing art or to throw more light on the nature of febrile diseases than a minute attention to the state of the temperature of the system'

In 1841 Andral[35] and, following him, Gierse,[36] plotted out a series of charts which they used in following the rise and fall of temperature as aids to the diagnosis and progress of disease Moreover they following Martine, took the precaution to obtain control charts of the temperature of normal individuals showing any rise or fall at various periods of the day and to compare these variations of temperature with those observed and noted in disease Then Hallmann,[37] Henri Roger, and, a little later, Demarquay[39] and Zimmermann,[40] obtained and studied numerous records of temperature from cases of typhus and typhoid fevers small pox, measles, erysipelas, whooping cough, tuberculosis, and pneumonia "as offering a simple basis for other observations free from all theoretical propositions Dr John Davy's observations[41] on temperature of healthy persons were most valuable, at a later date these were very fully discussed by Ogle[42]

---

[*] See Sir Wm H Broadbent Brit Med Jour 1903 vol. i p 813.

To Bärensprung[43] and Traube[43] belongs the distinction of placing medical thermometry on a more sound footing, of coördinating and interpreting what had hitherto been put forward in isolated, imperfect, or framentary form, and of raising clinical thermometry "to the dignity of a comprehensive, well constructed, and, in many respects, complete doctrine" (Wunderlich) They demonstrated most clearly that in the thermometer the physician and surgeon had a means of deciding what, in those days, without our modern aids to diagnosis, were difficult and greatly debated questions in their art In this connexion Gamgee quotes Liebermeister[43a] as making important contributions on heat production and regulation in the warm blooded animals, at the same time making very appreciative reference to Jürgensen which we shall consider later

Dr David Livingstone[44] used the thermometer in South Africa at a very early date, for we find in his "Missionary Travels in South Africa" the following "The heat in the axilla, over the heart, and region of the stomach was, in my case, 100°, but along the spine and at the nape of the neck 103°" (p 194) The observations were made in 1853 and published in 1857, and it is of interest to note that he was convinced that the temperature of Africans was 2° F less than his own (p 509) "The bulb held under my tongue stood at 100°, under that of the native 98°" This, along with the numerous references to thermometry made by Edinburgh men, affords strong proof that clinical thermometry was taught and practised in the Scottish schools some years before it was systematically practised south of the Tweed Dr Warburton Begbie, for example, a physician in the Edinburgh Royal Infirmary, acquired his first clinical thermometer in 1857 and induced his pupil, Dr Brydon,[45] to make a prolonged series of observations with that instrument (similiar to that employed by Wilks) regarding typhus and typhoid fever

ADVANCE IN THERMOMETRY AS A ROUTINE CLINICAL PRACTICE

It is, however, to Carl Wunderlich and his classical work on temperature and disease that we owe the great advance in thermometry as a routine clinical practice that took place soon after the middle of the nineteenth century He accumulated an enormous mass of careful observations on temperature in disease, and, tabulating his results and studying them carefully, systematic thermometry in his hands became a recognised factor in clinical diagnosis, and important contributions to our knowledge of fever and other pathological conditions in which variations in temperature are involved were brought into great prominence

Wunderlich held that the normal temperature of healthy individuals is well nigh invariable

> A healthy man, whether fasting or digesting drinking water or stimulating fluids, employing mind or body or in a state of listlessness always retains his temperature [within half a degree] unless his health becomes disturbed In sleep the temperature of a healthy man is somewhat lower, but even then does not sink below 97 25° F

Wunderlich, however had foreseen the importance of a continuous 24 hour record, for we find that he insists that the temperatures met with in various diseases do not remain stable and unaltered during the 24 hours Fluctuations are observed these fluctuations being "in part dependent upon general rules, and in part determined by the nature, stage, and degree of the disease, or upon the increase or diminution of this"

It is now recognised that as regards the first of these statements we must accept as normal a much wider diurnal variation than was laid down by Wunderlich and those who followed him and copied his figures, whilst as regards the first point we are inclined, as the result of our experiments, to maintain that the exaggerated temperature variations induced by outside agencies are of prime importance, especially in the diagnosis of such diseases as tuberculosis, latent typhoid or pneumonia, and similar conditions "The uninterruptedly regular observation of the progress of the temperature throughout the whole course of the disease furnishes the most important indications for the judgment of febrile affections"

The influence of Wunderlich's work was felt almost immediately, paper after paper appeared in quick succession and of the medical journals the *Medical Times and Gazette* became the special channel of distribution of thermometric lore

It is, however, to Aitken's[46] advocacy of Wunderlich's work and to Allbutt's introduction of the clinical thermometer in its present form that we owe the rapid extension of clinical thermometry In the third edition of his "Practice of Medicine" Aitken gives a very complete account of Wunderlich's investigations, and in precise and succinct form defines for the practitioner some of the more important factors in thermometry He quotes Valentin (third edition, p 39) to the effect that all warm blooded animals surrounded by an atmosphere of 50° F have a temperature of about 99 5° in the back of the mouth, the rectum or other accessible *internal parts*, and at *completely sheltered parts of the surface* it is a degree lower—namely, 98 4° or 98 5° F Aitken points out that —

> In tuberculosis, especially in its acute form, the persistent maintenance of an uniformly high temperature will alone show that no arrest in the progress of the disease has occurred (p 48) Continuous daily observations by the thermometer thus teach the typical laws of particular forms of fever and supply the grounds or basis by which it is determined whether any individual case is progressing as it ought to do (p 47) It is rare, however that a definite diagnosis or prognosis can be based on a single observation (p 44) The amount of heat is also at first reduced after a *full meal* and the use of alcohol but it rises again as digestion advances (p 40) *Active exercise* (not carried to the extent of exhausting fatigue) raises the temperature proportionally to the degree of muscular exertion made (p 40)

Writing, in 1866, "On the Use of the Thermometer as a Guide in the Diagnosis of Pyrexial Diseases," Dr F W Gibson,[47] after indicating the work done by Wunderlich, refers to the chapter on the range of temperature in disease in Aitken's "Treatise of Medicine" as affording a new field of medical investigation

> Before 1858 'the real importance of daily records of the temperature of the body in such [pyrexial] diseases was almost unknown but Drs Parkes Jenner Ringer and others are labouring in the same field in this country and the day is not I think very far distant when the physician will consider the thermometer not less indispensable to him than the stethoscope or microscope and when the surgeon will not neglect the observations of the temperature since Billroth has brought forward sufficient proofs of its great importance as an assistance in the diagnosis of surgical diseases '

Following Wunderlich he gives the normal temperature as 98 5° F, and assents that it may rise for a short while above, or fall slightly below this even in the healthy individual, but a permanent rise above 99·5° F or fall below 97·3° F "is a sure sign of disease" He points out that exposure even in a fairly warm room induces a fall, as do also a full meal and the use of alcohol, but that there is a rise of temperature as digestion advances and that temperature is lowered by sleep Finally, he claims that temperature is a much more certain guide to the pyrexial condition than is the pulse rate, and that although the two often rise and fall together, this is by no means invariably the case, and instances the frequency of the pulse induced by weakness which is accompanied by a distinct lowering of the body temperature He records that Mr Griffin, Mr Casella, and Messrs Negretti and Zambra all manufacture most excellent thermometers, and refers to Dr Aitken's maximum self registering instrument, which does not require to be read *in situ*, but may be removed and inspected when convenient

Investigations on the Bodily Temperature.

One of the most important of the papers that appeared about this time was a contribution to the subject by William Ogle, M.D[42] This observer set out to obtain for man a standard normal temperature with which the temperatures met with in disease might be compared, to see what diurnal fluctuations might occur, and to determine the conditions on which such fluctuations might depend.

After referring to Dr John Davy's two similar series of observations,[43] he compares Davy's results with his own, and points out what he holds are considerable differences, though when he compares sets of records taken from two different individuals he gives differences as marked as those he mentions as existing between Dr John Davy's figures and his own Dr Ogle finds that the diurnal variations are greater in man than in the woman and run through a wider range In the woman the temperature at 8.30 in the morning is 98° F, it rises steadily until the afternoon (3 to 5 P.M) to 98·8°, and from this point it falls until midnight to 98° No early morning temperatures were taken In the man the temperature at 8.30 is about 3/10° lower than in woman, the highest point is reached at from 6.30 to 7.30 in the evening, and there is a steady fall until after midnight to 97·9° or 98° On continuing the observations through the night it is found that the lowest temperature recorded, 97·2°, is between 6 and 6.30 A.M, and that from this point there is a steady rise These variations always recur in the same individual whilst in health within a certain small range, 3/10°, though—

> In one person the maximum heat was attained at an earlier period in the day than was the case with the other, and this peculiarity recurs each time. So in one person the morning temperature was considerably higher than in the other and this difference is repeated in each of the three months

He maintains that the lowest temperature of the body occurs about daybreak, that after the maximum is reached in the afternoon or evening the change in temperature is at first slow, except when wine is taken but becomes more rapid after 9 or 10 o'clock and continues till daybreak, when the cycle begins again He found that the average diurnal variation is about 1·5° F, and hints at the effects of external cold and heat on the body temperature He also discusses the effects of food and exercise and functional metabolic activity Short exposure to cold raises the internal temperature but prolonged exposure has the opposite effect, as also has exposure to temperatures higher than that of the body He agrees with Davy that exercise raises the temperature of the body—of the extremities much more than that of the internal organs As regards food, he notes that both breakfast and lunch are followed by a considerable rise of temperature, but that there is usually a marked and rapid fall after dinner, and he thinks that this latter may be due in some measure at any rate, to the "gradual cooling of the body heated by exertion. But this is not the whole explanation." He found that claret taken at dinner was always followed by a rapid fall of temperature, though after a time there was some recovery, and, indeed, that in some cases the temperature rises after alcohol has been taken to a point that cannot be considered normal. Tea, on the other hand, retards the fall very considerably The greater part of the rise of temperature is due to the combined influence of exercise and metabolism, The "organic functions" which correspond more or less closely with those of animal life have a period of repose which is "less perfect and begins and ends earlier" than that of the functions of animal life

In a series of unsigned articles on the thermometer in disease that appeared in the *Medical Times and Gazette* during 1866, the importance of the use of the thermometer in different diseases is, as above indicated, referred to, and it is insisted that "in every case of fever, no matter from what it originates, the temperature is elevated, and this elevation of the temperature is the only constant symptom of fever" Instructions and warnings are given as to the use of this instrument The temperature should be taken twice in the day, at 8 A.M. and 8 P.M., and it is stated that it is better to use a thermometer constructed for the purpose, those of the ordinary make being often untrue and always difficult of application It is pointed out that in health there may be an elevation amounting to 2° or 2·5° F, from a minimum temperature of 97° to a maximum of 99° or 99·5°, and that the daily variations of the temperature in health are greater in young people than in adults, that the lowest temperature is reached usually between 12 P.M and 4 A.M., and a maximum about 12 noon, and that all this must be taken into consideration in interpreting the temperature in cases of disease

The importance of a rise of temperature in inflammatory and tuberculous conditions is insisted upon "While tubercle is being deposited in any of the organs of the body the temperature of the patient is preternaturally raised," and the writer continues "Temperature is a measure of the rapidity with which tubercle is being deposited in any of the organs of the body" If there be a chronic elevation of the temperature and this be not due to rheumatism, ague, suppuration, or chronic induration of the lung, such an elevation must be considered to be due to a tuberculous deposit in the body

In the June number of the same volume Dr F W Pavy, F R.S,[44] describes a case which, he argues, justifies the employment of the thermometer as a means of affording information in disease and as exemplifying "the extent of variation of temperature that may be in the course of disease within a few hours produced, and of the precision with which thermal manifestations transpire

SUMMARY OF OTHER INVESTIGATIONS

Sydney Ringer, M D, and Walter Rickards, M D, in a work "On the Temperature of the Body as a Help to Diagnosis in Tubercular, Cancerous and Other Forms of Consolidation of the Lungs,"[50] point out that the *temperature of the body* is always preternaturally elevated while tubercle is being deposited in any of its organs, a condition wanting, they maintain, in cases of cancer unless associated with the formation of abscess and the production of pus

Dr J S Warter, in 1866,[51] writes —

> In health there is a normal daily elevation *often from 2 to 2 5 degrees Fahrenheit*, the morning temperature being the lowest and the evening one the highest. A full meal and the ingestion of alcohol is also said to lower *pro tempore* the heat of the body

He maintains that sufficient information may be obtained from a single observation per diem made at midday The claim that observations should be made at the same time each day is thoroughly sound, whether these observations are made once or twice a day, but there is little doubt that he is in error in assuming that these one or two daily observations are sufficient for all clinical purposes, an error that soon became patent to intelligent clinicians

During the epidemic of cholera in London in 1866 Mr F M Mackenzie made "Notes on Various Subjects Connected with Cholera as Observed in the London Hospital" (Appendix to vol III of the "Clinical Lectures and Reports by the Medical and Surgical Staff of the London Hospital," London, 1866) These notes contain a statement of the temperature observed in the armpit and in the rectum or vagina respectively in 40 cases of "extreme collapse" The average temperature of these cases was 94 9° F in the armpit and 100 6° in the vagina or rectum, whilst the extremes of temperature noted were 91 2° and 105 6° In the groin the temperature is about 2° higher than it is in the armpit (quoted by Chapman)[52]

W Ainslie Hollis, M B Cantab, in 1867[53] contributed a series of excellent observations made with thermometers manufactured by Smith and Beck and by Casella, two of them curved, three of them straight registering instruments

> As a rule, even in acute diseases I rarely *exceeded a single observation daily*, in chronic *cases one* or two *observations a* week were usually sufficient The hours selected were various, but *as nearly as might be the same for each case*

We can scarcely agree with the following —

> I cannot allow this subject to pass [he says] without strongly reprobating the practice of taking in severe cases several (sometimes even hourly) observations in the day, this *nimia cura medici* (if worthy of the term) can do no commensurate good to science compared with the *incon*venience, not to say distress, which it occasions patients who have to submit to it

He gives lists of the morbid or vital processes which "probably tend (*a*) to lower and (*b*) to increase the temperature of the body

A series of most valuable papers on temperature was contributed by E Long Fox,[54] who claims that the thermometer rightly used may be of the greatest value to the busiest practitioner and in many cases "paradoxical as it may sound will save his time He makes a reservation, however that too much must not be expected from the thermometer and that, "as a preliminary remark it is useful to remember that, for all persons, under all conditions the normal temperature is so nearly the same as only to vary by about 1° Fahr," and that "pathological temperature is embraced within the limits of about 15 3° F," that the temperature of 100° indicates fever, one of 96 8° "as indicating an algide condition due to some depressing influence," such as those immediately following acute disease in debilitated subjects, the use of drugs, hæmorrhage *prolonged vomiting and diarrhœa, and rigid* diet in convalescence, all *of which he claims are* causes *of a more or less temporary character* Causes *of more persistent type are disturbed* circulation *from organic* disease of the heart, diseases interfering *with the respiration*, the agony of certain diseases, alcoholism and chronic uræmia in which owing *to* the toxic condition of the blood oxidation of the tissues is interfered with, malnutrition due to the interference with the ingestion of food, dropsy and anæmia and certain chronic morbid conditions of the brain such as melancholia and dementia He points out, however, that it is specially useful where there is a rise of temperature, and in his long series of articles indicates that the character of the temperature may be of great value in diagnosis, instancing the regular ascent, prolonged stationary period, and gradual defervescence of enteric fever He points out the character of the temperature curve in relapsing fever, and maintains generally that the higher the temperature the more serious the prognosis

Further, it is on record that "*Staff Surgeon* Remond[55] of the late Hanoverian Army, *used* thermometry *in ascertaining the health of recruits*, malingering, and in determining *questions of* service and *transport*"

About this time Goodhart,[56] who was *evidently* stimulated by Aitken and Wilks *to study* Wunderlich's work and then to make *observations* on his own account, says —

> At the present time many look upon this instrument [the thermometer] as very interesting in the study of the natural history of disease, but as a thing of *comparatively little* value for the everyday work of *medical practice It may be that* too much was expected and *asked of it*, that the estimation of temperature *as an aid to diagnosis* was such a rational idea *that no adverse criticism* was ever offered on the introduction *of the thermometer* and that *at once* without proof or warrant its advocates were allowed to claim *for it a use* in every possible disease *From this one extreme we have gone* nearly to an opposite and *there are reasons for saying* that now in many instances the *temperature does not guide us as* much as it might do and that auscultation and *thermometry* do not go hand in hand *as they would do had every member* of our profession made *trial for himself of the latter mode of* investigation

Charts are given of temperatures taken once a day, then twice a day, morning and evening, and of surface temperature above, below, and on an abscess swelling Goodhart, in describing his experiments, writes —

> The condition of the skin whether dry or moist has some influence on the ascent of the mercury in the latter state the rise is usually slow while with *a dry and pungent* surface as in pneumonia it is sudden *An apparent contra*diction to this statement is *sometimes observed* in patients during the last *stage of typhoid* and other diseases in whom while *sweating profusely* the temperature may rapidly *rise* to a great height

He gives an interesting summary *of his observa*tions on temperature in disease *made during* 12 months, on the influence of drugs *over the* progress of disease and on the *practical points* that he has observed in connexion *with thermometry* as an aid to diagnosis, prognosis, *or treatment* (p 374)

INTRODUCTION OF IMPROVED CLINICAL THERMOMETERS

Clinical thermometry, however, as already noted, became practicable and popular only after the introduction of the clinical thermometer in its present form Clifford Allbutt,[57] reviewing Wunderlich's work in the *British and Foreign Medico Chirurgical Review* for April and July, 1870, gives a brief account (op cit, vol xlv, p 437) of his share in the introduction of the thermometer into general practice. He writes —

> The first clinical thermometers made in this country were those of Casella under the direction of Dr Aitken They were, however too cumbrous for general practice, and for this reason the thermometer long remained a stranger to the busy practitioner A few years ago I applied to Casella, but he had no pocket thermometers and seemed indisposed to make them I therefore set to work with Messrs Harvey and Reynolds to manufacture one and it was not so easy as it may seem to devise an accurate thermometer of a new form, and with a safe and portable case

The sale of the instrument, at first slow, increased rapidly, and Hawksley and others soon began to make and sell it All were graduated on the Fahrenheit scale, and a venture, made at Dr Allbutt's suggestion, with thermometers having Centigrade scale "stopped the sale promptly," for Harvey and Reynolds "made an instrument having both scales upon it, but no one bought it," and he continues "When I first designed pocket-thermometers I made them to fit within stethoscopes, but I did not like the results nor did others"

Dr Willson[58] writes —

> In 1864 I attended a number of cases of typhus My principal, Mr Leonard possessed a clinical thermometer, small and neat non registering the index on an ivory plate, below which the bulb protruded about 1 in. for placing in the mouth or axilla I used this instrument on several occasions

In 1868 *Potain*[59] described a very convenient and portable form of thermometer which he had contrived 11 or 12 cm long and the thickness of a quill It recorded quickly (two or three minutes) and was graduated to 0 1° C with the scale marked on the glass Coloured alcohol was the material used

A writer in the *Medical Times and Gazette* in 1868 draws attention to Allbutt's 'most excellent little self registering thermometer which is now being extensively used throughout the country, and cautioning those who use it not to expose it to a temperature of anything beyond 120° F He mentions certain thermometrical observations made by Mr Teale from which he concludes that—

> In many instances disease may be recognised by local changes in temperature, as for instance when it is suspected that a joint is inflamed the comparison of its temperature with that of the healthy one on the other side may lead to a correct diagnosis

In a letter dated Oct 19th, 1869, L P Casella[60] states that Professor Phillips, of Oxford, exhibited for the first time at the Great Exhibition in 1851 a self registering thermometer, the principle of registration 'being by means of a speck of air extracted from the mercury of the bulb, and, after completion of the instrument, so placed as to detach any required length of mercury to be used as an index." It is a convenient form of portable registering thermometer but received little notice at the time He continues —

> Dr Aitken of the Royal Victoria Hospital, Netley was directing his attention to the influence of heat on the human frame The sight of one of these thermometers was, I believe, the chief cause of my introduction to that gentleman, and through his kind coöperation "the self-registering clinical thermometer" was quickly and, I must say, most judiciously arranged, the length being about 10 inches, for the double purpose of having the degrees expanded and keeping the graduations a sufficient length from the bulb

In 1869 a new clinical thermometer appeared. THE LANCET of July 3rd, 1869, p 12, in a short note states —

> A handy clinical thermometer has been devised by Mr Hawksley, of Blenheim street, late foreman to Mr Baker of Holborn. It is about the size of Dr Allbutt's thermometer, and is graduated in fifths of a degree Fahr

The wooden cases was marked with comparative scales of Fahrenheit and centigrade and also scales of inches and eighths of an inch.

Dr B Cornelius Fox,[61] in "Remarks on Clinical Thermometers" in 1869, described the various thermometers then in use, criticising their manufacture in some cases very strongly He noted the inaccuracies of readings of the thermometers supplied by different makers, even with those sold with Kew Observatory certificates, and he concludes by trusting "that the preceding remarks will tend to create an interest in the employment of the thermometer amongst those who have hitherto felt none, and will, moreover, intensify the interest of all who study such an exceedingly important subject as 'the thermometry of disease'"

MEDICINE WITHOUT THE AID OF THE THERMOMETER

From this time onwards clinical thermometry gained rapidly in usefulness and popularity, though Wilks,[63] in his "Biographical Reminiscences" (p 143), commenting on Goodhart's paper on Thermometric Observations in Clinical Medicine,[65] says the instrument at that time had not come into general use, and, writing in 1903, he states that—

> In 1870 he 'requested the Superintendent at Guy's to procure a clinical thermometer I think it was *nearly a foot long* [the italics are ours] and was so great a novelty that it was taken to a South Eastern meeting of the British Medical Association for exhibition, where the members regarded it with much curiosity and interest although, I am sorry to say, one or two with ridicule." "It was at the service of anyone who might wish to make use of it"

He believes that the section in Dr Aitken's 'Practice of Medicine' setting forth the value of thermometry in clinical investigation, in accordance with the researches of Wunderlich, was the first that appeared in any treatise of medicine published in this country, and caused the new method to be widely known, "at all events it was from the knowledge therein gained" that he (Wilks) was led to make the above request to the 'Superintendent at Guy's" That clinical thermometry had made little headway in the United States up to 1865 is borne out by Garrison's[10] (p 639) statement that "neither Keen nor Tyson saw a clinical thermometer or a hypodermic syringe during 1862–65 Billings, however, in taking care of the wounded from the seven days before Richmond (1862) had provided himself with both'

It is only when we come to realise that the physicians and surgeons of those days had to make their diagnoses, carry on their treatment, and form their prognoses without having at command what appears to us to be an almost essential instrument of precision, so necessary has its use become to the modern clinician, that our respect for these older physicians and surgeons and their power of diagnosis attains its full measure

Bibliography (*Part I*)—1 Martine (1740) Essays, Medical and Philosophical London 1740 A collection of six essays four of which were reissued together as a second edition, Edinburgh 1772, *with the title* Essays and Observations on the Construction and Graduation of Thermometers and on the Heating and Cooling of Bodies This went through a number of editions the Cambridge University possessing a copy *of the* 4th ed Edinburgh, 1787 This writer also published in 1740 De similibus animalibus et animalium calore libri *duo*" Gamgee following Wunderlich ascribes a work of this date and with almost identical *title to Charles* Martin *but* confesses he has not been able to see a copy 2. THE DR DAUBER MEMORIAL NURSES' PRIZE FUND—As we have previously announced, it has been thought desirable to raise a *Memorial Fund to perpetuate* the memory of *Lieutenant* Colonel J H Dauber R A M C, *an* obituary notice of whom appeared in our columns on Sept 25th 1915 He was in command of the East Anglian Clearing Hospital but lost his life in the sinking of the transport ship *Royal Edward* on the way to the Dardanelles in August last Almost one of the last things that Dr Dauber did, revealing his public spirit was to write an important letter to *The Times* of July 9th, 1915 calling attention to the dissipation of strength by municipal and public bodies in expenditure on local undertakings not necessary to our military success which he maintained should be our one thought aim and hope The sentiment is to-day more than ever true. Dr Dauber was for many years lecturer to the nursing staff at the Soho Hospital for Women and the training of the nurses on the theoretical side of their work was entrusted entirely to him It has been decided to institute a fund to be called The Dr Dauber Memorial Nurses' Prize Fund " the income to be applied yearly in distributing prizes to the members of the nursing staff of that hospital It is hoped to raise a sum of about £250 Donations should be sent to the secretary, Mr Alfred Hayward, Hospital for Women Soho square London W

ON THE BACTERICIDAL POWER ACQUIRED BY THE SERUM AFTER THE ADMINISTRATION OF SALVARSAN OR NEOSALVARSAN

BY S R. DOUGLAS, M.R C S, L.R C.P LOND,
CAPTAIN I.M.S (RETIRED) FIRST ASSISTANT BACTERIOLOGICAL DEPARTMENT MEDICAL RESEARCH COMMITTEE, NATIONAL INSURANCE ACT
AND
L COLEBROOK, M.B, B S LOND,
CAPTAIN R.A.M.C. (T)
(From the Inoculation Department, St Mary's Hospital, London)

SHORTLY after the introduction of salvarsan as a curative agent for syphilis it was noticed that lesions secondarily infected with pyogenic cocci yielded to the treatment almost as promptly as those in which such secondary infections were absent Investigations carried out in this laboratory showed that such recoveries were not associated with any increase of the antibacterial powers of the patient s blood fluids, as measured by the opsonic index. Taking these facts into consideration, together with the well known antiseptic qualities of many arsenic compounds, it was suggested by Sir Almroth Wright that it would be of interest to ascertain if the serum acquired a bactericidal action after the administration of salvarsan or neosalvarsan

Shortly before the preliminary experiments were made by one of us (S R D) to demonstrate this bactericidal power, Wright had completed some researches on a quinine derivative,[1] now known as optochin, which had been shown by Morgenroth to be capable, when introduced into the blood, of killing off pneumococci in infected mice Wright by means of these experiments, which were carried out *in vitro*, was able to demonstrate that optochin was apparently just as active in its bactericidal power against the pneumococcus when in solution in serum or blood as when dissolved in water or saline solution, and that it was, in this respect, unlike other chemical bactericidal agents

Ehrlich had already enunciated the theory that the curative power of salvarsan and neosalvarsan in regard to diseases caused by spirochætes was due to these drugs having either a greater affinity for the spirochætes than for the tissues or the blood, that is, in the technical phraseology, it was more parasitotropic than histo or sero tropic, or, even if the drug did enter into combination with the blood or tissues, this combination was so loose that in the presence of the parasite dissociation took place, thus allowing the drug freedom to act on the parasites

These experiments of Wright s suggest that such theories were applicable to the whole range of chemo, or as he prefers to call it pharmaco therapy It was therefore decided before further investigating the bactericidal action of patients' serum after the administration of the drug to ascertain by a series of similar experiments whether salvarsan and neosalvarsan were more bacteriotropic than sero or hæmocyto tropic

In Vitro Experiments

The methods used in these investigations were as follows —Dealing in the first place with neosalvarsan a 1 in 300 watery solution was made To test the bactericidal power of the various mixtures made with this "stock" solution of neosalvarsan a 24 hour old broth culture of staphylococcus was used

Preference was given to the staphylococcus over other organisms in this and in many of the following experiments, firstly, because of the ease with which young broth cultures can be accurately diluted, secondly, because serum has little or no bactericidal action against it even in highly immunised individuals, and, thirdly, this organism having a very considerable resistance to most antiseptics, if positive bactericidal results were obtained, it might be safely assumed that very many other organisms would be similarly affected.

The reservoir of a Wright's bactericidal pipette[2] having been filled in with broth, a mixture made of 1 volume of the solution to be tested and 1 volume of the dilution of the staphylococcus culture was drawn up into the capillary portion. After incubating the tubes overnight at 37° C the contents of the capillary portion were drawn up into the broth contained in the reservoir Further incubation at 37° C indicated by the presence or absence of growth whether the various solutions containing the neosalvarsan had killed off the staphylococci or not

The various mixtures containing neosalvarsan which were tested for their bactericidal power were I The 1 in 300 solution of neosalvarsan diluted ten fold with salt solution II This same solution diluted ten fold with serum. III This same solution diluted ten fold with blood. The blood was then allowed to clot, and the serum which exuded from the clot was the fluid tested The results obtained are set forth below in tabular form (Table I) —

TABLE I.

Dilution of the broth culture of staphylococcus which contained 260 000 000 cocci per c c	I 1 in 300 solution of neosalvarsan diluted ten fold with salt solution	II 1 in 300 solution of neosalvarsan diluted ten fold with serum	III 1 in 300 solution of neosalvarsan diluted ten fold with blood.
1 in 1 000 000	Sterile	Sterile.	Sterile
1 in 100 000			
1 in 10,000			"
1 in 1 000		Growth.	"
1 in 100		"	Growth.
1 in 10	Growth.		

This experiment shows that the 1 in 300 solution of neosalvarsan, diluted with normal saline solution, was considerably more actively bactericidal than when the same 1 in 300 solution was diluted with an equivalent amount of serum or blood It further indicates that the serum has a greater effect in inhibiting the bactericidal power than is possessed by the blood, which suggests the fluid constituents of the blood being the binding agents rather than the corpuscles

This same experiment was then carried out with fluids containing salvarsan A 1 in 300 solution of salvarsan was made and carefully neutralised with sodium hydrate From this solution the following mixtures were made I The 1 in 300 solution of salvarsan diluted ten fold with normal saline solution II The same solution diluted ten fold with serum III The same solution diluted twenty fold with blood, which was then allowed to clot The serum thus obtained was used for the test

It is to be noticed that mixture No III was made by adding 1 volume of salvarsan solution to 19 of blood, instead of, as in the case of the test applied to the neosalvarsan, making a 1 in 10 dilution with blood This was done in view of the fact that the corpuscles represent about half the volume of the blood Again the bactericidal power was tested against a culture of staphylococcus The bactericidal tubes were incubated for one hour at 37° C after the mixture of culture dilution and the fluid containing the salvarsan had been introduced into the capillary portion instead of, as in the case of the experiment carried out with neosalvarsan, being left overnight The results obtained with these mixtures of salvarsan are given in tabular form (Table II)

[2] Technique of the Teat and Capillary Glass Tube by Wright London Constable 1912

TABLE II

Dilution of the broth *culture of staphylo-* coccus which contained 410 000 000 cocci per c.c.	I 1 in 300 solution of salvarsan diluted ten fold with salt solution	II 1 in 300 solution of salvarsan diluted ten fold with serum	III 1 in 300 solution of salvarsan diluted twenty *fold with* blood
1 in 1 000 000	Sterile	Sterile	Sterile
1 in 100 000			"
1 in 10 000			Growth.
1 in 1 000	"		
1 in 100		Growth	
1 in 10	Growth		

This experiment gives almost identical results as those obtained with neosalvarsan

In Vivo Experiments

These investigations were made with the sera of patients who were suffering from various manifestations of syphilis and to whom ordinary doses of salvarsan or neosalvarsan—that is 0 6 grm of the former or the equivalent of the latter—had been administered in the course of their treatment Neosalvarsan was used in eight of the cases, and it was found that in seven of these the serum developed a distinct bactericidal power against staphylococcus In one case the bactericidal power was also tested against a coli form organism with the result that it was found to be equally as well marked as against the staphylococcus In the one case in which no bactericidal power could be found the test was carried out against a very thick culture of B pyocyaneus and only one sample of blood was obtained after the administration of the drug The details of two of these experiments are given below

Experiment 1—The method employed for the demonstration of the bactericidal power was similar to that used in the *in vitro* experiments The organism used to demonstrate this power was staphylococcus, a 24 hour broth culture containing 150 millions living organisms per c c Four samples of blood were obtained The first, immediately before the injection of the neosalvarsan, the second, one hour after the injection, the third, two hours after the injection, the fourth, three hours after the injection The results obtained are shown in Table III

TABLE III

Dilution of culture of staphylococcus which contained 150 000 000 cocci per c c	Serum from blood before injection	Serum *from blood* 1 hour after injection	Serum *from blood* 2 hours after injection	Serum *from blood* 3 hours after injection
1 in 1 000 000	Sterile	Sterile	Sterile	Sterile.
1 in 100 000	Growth			
1 in 10 000	"			
1 in 1 000				*Growth.*

It will be seen that in this experiment 5 c mm of serum (that being the quantity of serum used in each tube) was capable of killing off at least 750 staphylococci one hour after the injection had been given, whereas the serum before the injection had no bactericidal power whatever

Experiment 2—Broth culture of staphylococcus 24 hours old containing 245 millions living organisms per c c Four samples of blood obtained The first immediately before the injection of neosalvarsan, the second one hour after the injection, the third two hours after the injection, the fourth three hours after the injection The results are given in Table IV

TABLE IV

Dilution of the culture of staphylococcus which contained 245 000 000 cocci per c c	Serum *from blood* taken before injection	Serum *from blood* taken 1 hour after injection	Serum *from blood* taken 2 hours after injection	Serum *from blood* taken 3 hours after injection
1 in 1 000 000	Sterile.	Sterile	Sterile	Sterile
1 in 100 000	Growth			
1 in 10 000			Growth	Growth
1 in 1 000		Growth		
1 in 100	"			

In this experiment 5 *c* mm of the serum obtained one hour after the injection was able *to* kill at least 122 staphylococci, whereas this quantity of serum before the injection could at the most have killed but one organism

It will be noticed that while both these experiments show that the serum has developed a very considerable bactericidal power, it is evidently but of short duration, for even after as short a period as two hours it has sometimes passed its maximum Wishing to make certain that the bactericidal power which was almost uniformly found to have developed in the serum was in no way connected with immune bodies, the serum of certain of the cases was again tested after having been heated to 60° C for about ten minutes a proceeding which would have rendered inert any such immune bodies contained in it

The results of one of these experiments given in Table V show that such a temperature was without any detrimental effect, so that it is certain that the lethal action of the serum was in no way connected with immune bodies

TABLE V

Dilution of staphylococcus culture containing 490 000 000 cocci per c c	Serum from blood taken before injection	Serum from blood taken 1 *hour after* injection	Same serum *heated to* 60° C for 10 *minutes*	Serum from blood taken 2 hours after injection	Same serum heated to 60° C *for 10 minutes*
1 in 1 000 000	Growth	Sterile	Sterile.	*Sterile*	*Sterile*
1 in 100 000					
1 in 10 000			"	*Growth*	
1 in 1000					Growth
1 in 100		Growth	Growth		
1 in 10					

In this experiment 5 c mm of serum obtained one hour after the injection was able to kill 2450 staphylococci

Passing now to review the results obtained after the administration of salvarsan, it is seen that contrary to what was expected from the results of the experiments carried out *in vitro* after the administration of this preparation, but little bactericidal power was found in the serum Thus, out of eight cases in which the serum was tested at various intervals of from ten minutes to three hours after the administration of the drug four were found to have developed no recognisable increase of bactericidal power Three of these were tested against cultures of staphylococcus, the other against the pneumococcus, one of those tested against the staphylococcus was also tested against the pneumococcus with a similar result Of the other cases three showed a slightly increased bactericidal power, in one case against the staphylococcus, in another against the pneumococcus, and in the third against staphylococcus and streptococcus The remaining case showed a similar slight increase of bactericidal power against a culture of streptococcus, but none at all against either staphylococcus or pneumococcus

It was noticed, however, in all these experiments, and especially in those in which staphylococcus cultures were used, that the samples of serum obtained after the injection of the salvarsan showed a marked power of inhibiting the growth of the organisms This was evidenced by the slowness of growth—two or even three days elapsing before it could be definitely ascertained if growth was present or absent, and also in those tubes where growth occurred the organisms were agglutinated into masses, so that instead of an even turbidity of the broth a small mass of organisms occurred in the bottom part of the reservoir

In view of the fact that the patients' serum in our experiments always showed a higher bactericidal power after the injection of neosalvarsan than of salvarsan, it is of interest to note that Swift and Ellis,[3] working with Spirochæta duttoni, were able to show a similar difference in respect of spirochæticidal power Further, they showed that patients' serum, after administration of these drugs, acquired a spirochæticidal power for only a few hours, reaching its maximum within the first hour after the injection, and that this spirochæticidal power was somewhat increased, rather than diminished, by heating the serum to 60° C (*cf* Table V above)

Summary and Conclusions

1 Neosalvarsan and salvarsan in watery solutions possess a very distinct bactericidal power against staphylococcus when the strength of the solution is 1 in 6000 When the solvent largely consists of blood or serum this power is slightly diminished The bactericidal power of solutions of both these preparations appears to be practically the same

2 The administration of neosalvarsan in ordinary doses renders the blood fluids markedly bactericidal This power lasts but a short time, and seems to reach its maximum about one hour after the administration of the drug, diminishing rapidly in the third and fourth hours

3 Heating the serum to 60° C for from 10 to 20 minutes has no deleterious effect on this bactericidal power showing that it is not in any way due to the development of immune bodies in the serum, and this fact, together with the short period in which the serum is found to be bactericidal, strongly suggests that the bactericidal power is due to some arsenic compound in solution in the blood serum

4 Salvarsan which as mentioned above, has almost identically the same bactericidal power as neosalvarsan in *in vitro* experiments, gave practically no demonstrable bactericidal power to the patient's serum when ordinary therapeutic doses were administered, but it was constantly noticed that organisms which had been treated with serum obtained within three hours of the administration of the drug grew very much more slowly than normally and were agglutinated into masses

5 In view of the very distinct bactericidal power which the serum acquires after the administration of neosalvarsan, it is reasonable to hope that the administration of this drug, or some similar preparation such as neokharsivan, would have a beneficial effect on wound or other similar septicæmias and might even strikingly assist in the sterilisation of deep and irregular suppurating wounds

A CONTRIBUTION TO THE BIOLOGY OF THE VERMIFORM APPENDIX

BY W COLIN MACKENZIE, M D MELB, F.R S (EDIN)

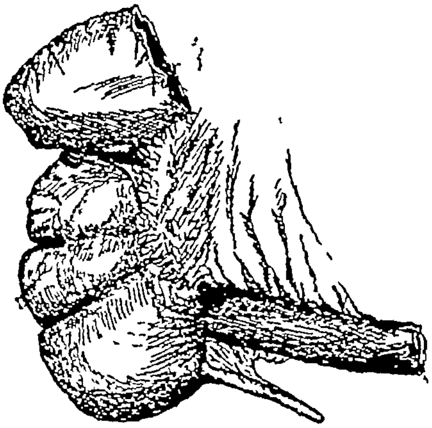
A STUDY of the fauna of Australia offers a unique opportunity in aiding the solution of many important biological questions, and especially those pertaining to the gastro intestine The two monotremes and the various marsupials represent the selected results of a struggle with forces that have been operating through many ages As the survival results among the marsupials are in many ways so diverse we have a distinct advantage in being able to institute comparisons among animals limited to the same order Furthermore, during the last century these animals—lowest on the mammalian scale—were suddenly brought into contact with modern man We are unfortunately now witnessing final phases in the struggle and their biological significances Amongst the marsupials we have on one side the koala, a purely eucalyptus leaf feeder with a cæcum which may reach the great length of 244 cm, and on the other the Tasmanian devil (Dasyurus ursinus), purely carnivorus, which has evolved a simple intestinal tube swung on a single mesentery, with no differentiation except microscopically between the large and small gut Both these are rapidly becoming extinct—the former in spite of a rigid protection Between these varieties we have the opossum (Trichosurus), more adaptable as regards diet than the koala, and hence still numerous in different parts of the continent, and the allied varieties of the Macropodidæ—viz, wallaby, the selected and more adaptable variety whose cæcum may resemble that of the human fœtus and be only 5 cm long, and the kangaroo whose cæcum—much more capacious—varies from 30 to 40 cm In addition we have Phascolomys (wombat), the selected marsupial, living on a nutritious diet of vegetable matter, whose abdominal contents resemble those of man and who shares with him and the higher anthropoids the possession of a true vermiform appendix. To those I propose to add the Echidna

What is meant by Vermiform Appendix

The appendices of these four types apart from size are difficult to differentiate, and subscribe to what Charles Bell and Owen refer to in the definition of the vermiform appendix as a small gut—appended to the cæcum and differentiated externally by a marked commencement and internally by a valvular structure—but bearing no relation in size or figure to any part of the intestinal canal, which, from its smallness and twisted appearance like the writhing of an earthworm, has received the name of "vermiform" As Stapley and Lewis in their important paper[1] write 'It did not occur to Owen on account of the presence of this massed lymphoid tissue to name the end of the rabbit's cæcum 'vermiform' He did not regard the rabbit as showing that rare form which he thought of under the name 'vermiform appendix'" The rabbit has a highly specialised intestine, since apart from the sacculus rotundus there are no less than six distinct areas in the great intestine, making it unfit for comparison Nor did Owen include Lemuroidea, as in his description of the aye aye he is careful to point out, nor did he refer to the appendicular ends of cæca such as one often sees in the phyllophagous koala and opossum, where I have never yet found a single lymphoid follicle

The Validity of Einar Lönnberg's View

FIG 1



Ileo-cæcal region Phascolomys mitchelli (All the figures are half natural size)

In 1902 Dr Lönnberg advanced the opinion[2] that if the wombat's appendix were a true vermiform appendage—i e , the reduced blind end of a cæcum—it ought to have opened into the cæcum of which it was a part, as it does not, but opens with a quite independent opening of its own near that of the ileum, he judges that the so called processus vermiformis of the wombat represents a rudiment of the whole cæcum, since it acquires a similar situation, opening into the colon in relation with the ileo cæcal valve A new cæcum becomes formed behind the cæcum, the result of a bulge of the colon owing to food alterations—viz , reversion to a more bulky diet Apparently Lönnberg's material was limited, as he tells us when discussing the colic sacculi he had worked on two animals, and further, his description might equally apply to the fourth variety of the human cæcum in which, according to Deaver, the internal sacculus has disappeared entirely and the base of the appendix is attached to the cæcum posterior to the receding angle between the ileum and the cæcum, the opening being sometimes in relation with the ileo cæcal valve Furthermore, we have no evidence that food alterations presumably recent have occurred A reference to Figs 1 and 2 in which the lumen of the appendix is patent, indicates the rotation taking place, and shows the base of the appendix corresponding to the true apex of the cæcum In Fig 3, where the internal opening which was not within the lips of the ileo cæcal valve has closed and the appendix is adherent to the ileum, not only has the left sacculus disappeared, but the right has atrophied almost up to the level of the ileum The average human cæcum, i e, one approaching the fourth type, has a depth of about 6 cm , and in the case of a young orang utang in the Hunterian Museum the depth of the cæcum is 2 5 cm and the width 4 5 cm It approaches the fourth type—the termination of the ileum running obliquely through the intestinal wall being in juxtaposition to the appendicular orifice An examination of a series of 12 Victorian wombats showed that the cæcal depth varied from 1 to 1 5 cm In two cases it was only 0 5 cm and in one case was actually on the ileal level In a latifrons with a well defined lumen, mesentery, and appendix the pouch was 3 cm deep, and in another (mitchelli) with the appendix obviously the apex of the cæcum the depth equalled 4 cm and the width 5 cm The lumen of the appendicular canal was incomplete in 64 per cent of specimens After the twentieth year 32 per cent of human appendices are obliterated The approximation of the base of the appendix towards the ileo cæcal valve is quite in accordance with the evolutionary trend of that organ Lönnberg believes such a movement took place Yet he would not admit of the classification of the wombat with man and the ape, because he believes a new cæcum has been formed, the result of supposed diet alteration To favour that view from the examination of a large number of specimens I have failed to find evidence that, apart from the formation of a new cæcum, even the right external sacculus has enlarged On the contrary, there is abundant evidence of atrophy (Figs 3 and 4) Owen s generalisation[3] that 'the cæcum in the wombat is extremely short but wide, it is

[3] Comparative Anatomy of the Vertebrates vol iii

remarkable for being provided with a vermiform appendage," must still be accepted

Types of Human Cæcum

The classical description of Sir Frederick Treves[4] still forms the basis of our comparison He recognised four types (*a*) Infantile, with muscle bands equi distant, (*b*) cæcum more quadrilateral, appendix appearing between two bulging sacculi, (*c*) apex turned to the left and posterior—the base of the appendix is brought nearer the ileo cæcal valve, a false apex formed by the highly developed part to the right, (*d*) sacculus to the right relatively large, while that to the left has disappeared—the root of the appendix appears to spring almost from the ileo cæcal junction No anatomist has ever suggested that the relatively large size of the right sacculus was the result of some reversion to a more bulky diet These four variations become intelligible—not mere statements of facts—if we recognise that each represents a coördinated sequence of the other, each is part of a coördinate scheme in the evolution of the appendix, and no one variation can be regarded as the type

Mode of Disappearance of Structures

It is interesting to note that the oldest known wombat's appendix, once the property of Sir Everard Home, is in the Hunterian Museum, and that John Hunter was known to be engaged on the marsupials just before his death. His work on absorbents shows that the question of disappearance of organs interested him "It may be difficult at first," he writes, "to conceive how a part of the body can be removed by itself, but it is just as difficult to conceive how a part can grow or *add to itself*, which we see daily taking place These are both certain facts A part which was necessary in one stage of life, but which becomes entirely useless in another, is removed It is evident in many animals the thymus gland is removed" It is clear that a knowledge of the mode of disappearance of normal structure should help us in the investigation of the abnormal Amongst the marsupials we notice the disappearance of the thoracic thymus in the wombat, but its good development in the Dasyurus ursinus the closure of the inguinal canal in the male sex of the latter though open in that of the former as well as in koala and the kangaroo the incorporation of the fibula into the tibia as seen in the Macropodidæ, the small relative size of the adrenals in the phyllophagous koala and Trichosurus and the approach of the right along the vena cava to the liver In the case of the opossum (Trichosurus) it may be found approximate to the liver under the capsule or be completely absent In the female the Müllerian ducts, though differentiated into duct, uterus, and vagina, nevertheless open separately into the urino genital sinus Yet from the upper part of the vagina on each side we have given off—beginning as a bend—the median vaginal cæcum which approximates so closely to that of the opposite side that fusion takes place—the two walls forming only an intermediate septum This breaks down so that one central vaginal cæcum or median vagina is formed which, increasing in size, reaches the urino genital sinus to serve for the transmission of the fœtus and remains the vagina of higher types[5] Thus we see formation and atrophy going on in the one order and the triple vagina of the marsupial becomes intelligible when we realise that the design is unification—the lateral vaginæ finally disappearing

Similarly by a study of the vermiform appendix in the wombat nature offers us the clue to the mode of disappearance of that structure in man since we can trace it from the fourth human type to complete disappearance (Fig 4) It may be found as in Phascolomys latifrons quite independent of the ileum with a well defined mesentery, or the mesentery may be only partial and the base be in relation with the termination of the ileum or the mesentery be altogether absent As shown in Fig 3, the appendix finally becomes incorporated into the wall of the ileum and the various grades are seen till in one specimen no appendix is present—the only structure being a firm knob on a shred of mesentery In none of these specimens was there evidence of any inflammation Thus a complete coördinated sequence from the fœtal or infantile type of cæcum to one showing complete disappearance of the appendix is clearly demonstrated In the wombat about the ileo cæcal region a puckering is noted, producing sacculi and depression This is of interest when we consider that close together about the root of the mesentery we have duodenum, duodeno jejunal flexure, transverse colon, and with an interval of only 2 5 cm the ileo cæcal junction This association I regard as being dominated by the right vagus nerve

FIG 4

Cæcal Region in the Monotremes

When we consider the æons that have passed since the monotremes first evolved we have reason to congratulate ourselves that two, presenting such diversities, have remained—one the Platypus, content to remain in the mountain streams, and the other the Echidna, evolving on land, where the struggle for existence was more *intense*—thus no doubt accounting for the greater size of its brain and the development of convolutions and sulci

The intestinal tract in Ornithorhynchus might be described as a simple canal 5–6 feet in length and characterised by the presence of a slender cæcal tube 30–45 cm from the termination—there being no obvious distinction between the large and small gut, except histologically The cæcum is about 3 cm long, with a distinct mesentery (Fig 5), and, in all cases examined, free, with a well defined lumen continued to its termination The mesentery of the cæcum passes to the intestine on the side nearer the stomach Section of the middle of the cæcal tube shows a well defined circular but narrower longitudinal muscular layer In the submucous layer two nodules of lymphoid tissue are seen The mucous layer shows long convoluted tubular glands lined by cubical cells From the bile duct for a distance of about 3 feet we notice in the intestine tubular glands lined by columnar epithelium and convoluted glands leading up to the base of elongated finger like *projections* with pro cesses resembling villi In the sections in the vicinity of the cæcum no villi are present, the gut on *either side of the cæcum* presenting similar features to it—viz, the long convoluted tubular glands, *except that there is* more lymphoid tissue in the *cæcum* As we *progress to* the cloaca the gut tract takes on more the character of mammalian large gut[6] It seems that the cæcum in the Platypus can be regarded as an extremely primitive organ presenting practically similar structure to that of the surrounding intestine Here apparently nature gives us a clue to future intentions in the creation of an accessory tube capable of expanding according to the needs of digestion, till in a land animal a little higher in the scale (koala) it reaches the enormous length of 8 feet and a circumference of 15 cm What developments took place among mono tremes in the struggle *for a land existence* we are unable even to conjecture In the Echidna the stomach, considerably larger than that of the Platypus may reach a length of 15 cm, and shows the mammalian character and not stratified epithelium as in the latter The total length of the intestinal tract varies *from 9 to 10½ feet, but there is a* macroscopic distinction between large and small intestine, and internally we can distinguish what Professor Keith[7] refers to as cæcal colon, into which the small gut and what I regard as a vermiform appendage (when patent) separately open This latter lies from 30 to 45 cm *from the termination* of the large gut on the dorsum of the commencement of the vestibule Its length varies from 1 5 to 3 5 cm, but compared with the cæcum of the Platypus a great character is variability as regards length, freedom, mesentery, and lumen In 35 per cent the lumen is incomplete, and the appendage could not be distended by compression of the intestinal content A trace of mesentery may be noted at the root of the appendix, but all specimens examined by me but one—which is free—were adherent to the wall of the *ileum*, as in the wombat, *this varying from an adherency* at the commencement up to half the extent In the specimen illustrated (Fig 6)—devoid of mesentery—which was 1 5 cm long, fully two fifths is incorporated with the ileum, the remainder being only a slender rigid stem without lumen I have found retrogression more marked in specimens from New South Wales than from Victoria. One specimen shows the appendix the seat of inflammatory change to which the omentum has been adherent, thus giving us a hint low down in the mammalian scale as to a function of this structure The examination of a typical section shows the muscle coats to be relatively small, though the inner circular is the larger, but the submucous tissue is largely replaced by lymphoid tissue This lymphoid tissue displaces also a considerable amount of the *mucous layer, in the glands of* which columnar and goblet cells are seen The *intestine on either side* is typical large and small mammalian gut, the appendix having the character of the large gut. It is interesting to note in connexion with the disappearance of organs that while both monotremes retain the thymus gland throughout life, this is *more evident in the Platypus In the thymus of a* male Echidna colloidal change has been noted

Significance of the Foregoing

That a group of animals—relics from a bygone age —should have remained to throw light on the early development of mammalian life is remarkable, and more so when we consider that in the one order we have a maximum cæcal development (koala), appendicular formation (wombat), and the simple intestinal tube (carnivorous marsupial) It is not without significance that the most adaptable animals are the Echidna—wombat—and wallaby The koala with his enormous cæcum and specialised diet is becoming rapidly extinct, and on the mainland it is almost impossible in Victoria or New South Wales to procure a carnivorous marsupial, while in Tasmania Dasyurus ursinus is scarce and the marsupial wolf has practically dis appeared In Victoria the wombat, so far from needing protection, is actually on the vermin list Nor is this to be wondered at when one compares the physical development of the latter with the Tasmanian devil, in which animal we are struck with the muscle pallor, tendinous change and the large deposit in parts of intermuscular fat If one were asked to designate the perfected physical type amongst the mammalia, the wombat might be unhesitatingly referred to, and Mr Le Souef, director of the Melbourne Zoological Gardens, has frequently commented on the great resistance of this animal to either injury or disease The wombat, far from dispensing with a large gut has actually one reaching the great length of

FIG 6

[6] On embryological grounds however the portion of intestine—about 12 cm long—between the cæcum and the attachment of the colon to the meso-duodenum must be regarded as large gut This portion is swung on the common mesentery The colon beyond is swung on its own mesocolon

[7] Human Embryology and Morphology Arthur Keith third edition

12 to 14 feet In the Macropodidæ this gut may reach 6 to 8 feet, while in the small Echidna 45 cm of large intestine may be met with The carnivorous marsupial, having the "ideal" simple tube with practically no large gut, is the least resistant of all

Biological teaching is plain—it is decidedly against the inutility of the large intestine It is also noteworthy that the ultimate disappearance of the appendix is a coördinate action and not necessarily associated with such frequent inflammation as we are witnessing in the human type As has been stated although a large number of wombats have been examined in no one case has any evidence of inflammation been seen, nor have I yet heard of an instance In the case of man the question arises, What is the factor interfering with proper coördination? Is the leakage dietetic or is it a question of environment or due to the erect posture? One scarcely expects surgery to give the reply

I wish to thank the President and Council of the Royal College of Surgeons of England for the privilege of carrying on research work in the Hunterian Laboratories and Major C V Mackay, R.A.M.C., for valuable help in the preparation of numerous dissections

NOTES ON FRIEDLÄNDER'S PNEUMOBACTERIUM[1]

By A R FRIEL, M D DUB.,
HONORARY PHYSICIAN FOR THE THROAT, NOSE, AND EAR, GENERAL HOSPITAL, JOHANNESBURG

WHEN a patient or an animal is inoculated with a bacterium there result various changes in the action of the serum of this animal *vis à vis* the bacterium and it is to these changes that we are in the habit of paying particular attention The changes which arise in the properties of a bacterium which has been subjected to the action of an immune serum are also worthy of study

Friedländer's pneumobacterium, which is present as a general rule in cases of ozæna, is usually very resistant to phagocytosis Most strains are quite insensitive when tested in the ordinary way of performing an opsonic test Even if the bacteria are exposed to the action of the serum of an uninoculated human patient for some hours, and then centrifuged down and made into an emulsion with a little salt solution and put up with fresh human serum and corpuscles, phagocytosis is very little indeed However, that they can be phagocyted, and in large numbers, can be shown by using the serum of a rabbit which has received two or three intravenous injections of a living or killed emulsion of B Friedländer This serum is so active that the bacteria are agglutinated and opsonised and if left long enough (one hour) in contact with the serum are dissolved To prevent the bacteriolytic action of the serum taking effect it can be heated to 56° C for half an hour

If one volume of B Friedländer be mixed with five or six volumes of inactivated immune serum and allowed to stand for three or five hours at room temperature and if the clump of bacteria which has formed by then be removed and washed in salt solution and planted on a sloped agar culture tube a good growth will have taken place by the following day If this process is repeated for a few days it will be found that a marked change has taken place in the bacterium, and this change is preserved for several further subcultures without further treatment with immune serum The bacterium can now be slightly agglutinated and readily opsonised by ordinary human serum.

To show the extent of this change the following table is of use An opsonic test was performed in the ordinary way, using one volume of an emulsion of Friedländer bacteria, one volume of serum and one volume of corpuscles and incubating for a quarter of an hour —

No		
0	Original strain	1 bacterium in 50 cells
1	Planticated	59 bacteria ,,
2	,,	2 ,,
3	,,	57 ,,
4	,,	51 ,,
5		4
6	,,	60
7	,,	132 ,, ,,
8	,,	177 ,, ,,
9	,,	149 ,, ,,
10	,,	144 ,, ,,

In the first few experiments the serum used for sensitising the bacteria prior to growth on a culture tube was unheated, but in the later experiments it was heated To designate this particular quality or property of bacteria the *descendants* of "sensitised" organisms the word "plantic" is suggested It is derived from the Greek πιαντικός, fat, the idea thought of being fattening an animal previous to slaughter

In treating patients suffering from ozæna I find that to get rid of the Friedländer infection it is advantageous to give the vaccine intravenously, and I am in the habit of using as a dose two millions of a sensitised non sterilised emulsion in salt or distilled water, which is injected into a vein at the bend of the elbow or in the forearm

Sensitisation is effected by using the serum of an inoculated rabbit and then centrifuging the bacteria down and re emulsifying in salt solution or distilled water If agglutination is very marked it is necessary to use distilled water to ensure a homogeneous emulsion The bacteria are counted before mixing with serum as it is not possible to do this afterwards on account of agglutination A dose of two millions or thereabouts is small enough to avoid the production of severe constitutional symptoms such as bad headache and vomiting, and large enough to cause slight malaise It need not be much increased and can be repeated at intervals of three or four days for a few times The improvement in the patient's condition is marked

In seeking for an explanation of why an intravenous injection of Friedländer is superior for purposes of treatment to a subcutaneous one, it may be noted that if a rabbit receives a large dose of these bacteria intravenously and the blood be examined at intervals till no bacteria are detected and then the rabbit be chloroformed and killed and smears made from the liver, kidneys, muscles lungs, and bone marrow, it will be found that the bacteria are in great numbers in the liver cells, some are also to be seen in the kidney, but practically nowhere else It may be that for the production of some immune bodies an internal organ such as the liver is an essential factor and submucous layer two nodules of lymphoid tissue are seen The mucous layer shows long convoluted tubular glands lined by cubical cells From the bile duct for a distance of about 3 feet we notice in the intestine tubular glands lined by columnar epithelium and convoluted glands leading up to the base of elongated finger like projections with processes resembling villi In the sections in the vicinity of the cæcum no villi are present, the gut on either side of the cæcum presenting similar features to it—viz, the long convoluted tubular glands, except that there is more lymphoid tissue in the cæcum As we progress to the cloaca the gut tract takes on more the character of mammalian large gut[6] It seems that the cæcum in the Platypus can be regarded as an extremely primitive organ presenting practically similar structure to that of the surrounding intestine Here apparently nature gives us a clue to future intentions in the creation of an accessory tube capable of expanding according to the needs of digestion, till in a land animal a little higher in the scale (koala) it reaches the enormous length of 8 feet and a circumference of 15 cm What developments took place among monotremes in the struggle for a land existence we are unable even to conjecture In the Echidna the stomach, considerably larger than that of the Platypus may reach a length of 15 cm, and shows the mammalian character and not stratified epithelium as in the latter The total length of the intestinal tract varies from 9 to 10½ feet, but there is a macroscopic distinction between large and small intestine, and internally we can distinguish what Professor Keith[7] refers to as cæcal colon, into which the small gut and what I regard as a vermiform appendage (when patent) separately open This latter lies from 30 to 45 cm from the termination of the large gut on the dorsum of the commencement of the vestibule Its length varies from 1 5 to 3 5 cm, but compared with the cæcum of the Platypus a great character is variability as regards length, freedom, mesentery, and lumen In 35 per cent the lumen is incomplete, and the appendage could not be distended by compression of the intestinal content A trace of mesentery may be noted at the root of the appendix, but all specimens examined by me but one—which is free—were adherent to the wall of the ileum, as in the wombat, this varying from an adherency at the commencement up to half the extent In the specimen illustrated (Fig 6)—devoid of mesentery—which was 1 5 cm long, fully two fifths is incorporated with the ileum, the remainder being only a slender rigid stem without lumen I have found retrogression more marked in specimens from New South Wales than from Victoria. GASTROTOMY IN A BABY AGED 6 MONTHS

BY C P G WAKELEY, M.R C S, L.R C.P LOND,
HOUSE SURGEON KING'S COLLEGE HOSPITAL SURGEON R.N

THE patient, an infant aged 6 months, swallowed an open clasp brooch two days before being admitted to hospital. On admission the child was X rayed and the brooch was seen to be situated in the lower third of the œsophagus, it was noticed that the brooch was open with the head of the pin projecting towards the mouth. An attempt was made to close the brooch with the aid of a bronchoscope, but it was pushed down into the stomach, as was verified by a second X ray photograph. The condition of the patient was not very good She had not taken the breast well since the brooch had been swallowed and had vomited at intervals The next day the baby became very collapsed, but her condition improved on subcutaneous saline infusion, however, her temperature suddenly went up to 107·2° F, pulse 192, and respirations 84 It was decided to operate

A median incision was made above the umbilicus, the stomach was found and carefully drawn out of the wound, and the rest of the peritoneal cavity packed off with hot sterile towels The pin part of the brooch was seen projecting through the anterior wall of the stomach near the greater curvature There were some isolated flakes of coagulated lymph covering the peritoneal surface of the stomach near the site of perforation. An incision was made over the brooch in the long axis of the stomach and the foreign body removed. The interior of the stomach was very congested and in a semi ulcerated condition The stomach wound was closed by Czerny-Lembert sutures and the abdominal wound closed without drainage The baby was kept in a tent bed for the next five days, and was fed by her mother 12 hours after the operation

A drachm of the following mixture was given every four hours for the first five days after the operation to relieve the ulcerated condition of the stomach Bismuth carbonate, 5 gr, sodium bicarbonate, 1½ gr, spirit of chloroform, 1 minim, tragacanth, in powder, ¾ gr water to 1 fl dr

The child was fed by her mother every four hours night and day, she vomited slightly after the operation The abdominal wound healed well and the little patient left hospital three weeks after the operation with a normal temperature and pulse. The hyperpyrexia on the day of the operation is very interesting, and the child was very fortunate to pull through after such a condition.

I have to thank Mr A Boyce Barrow, not only for kindly allowing me to publish this case, but also for permitting me to perform the operation in his absence

Discussion on "Soldier's Heart"

A MEETING of this section was held on Jan 18th, Lieutenant-Colonel W HALE WHITE, R A.M.C (T F), the President, being in the chair The subject under discussion was "Soldier's Heart"

SIR JAMES MACKENZIE, in opening the discussion, said it may well be recognised that the trying life to which a soldier was exposed placed a strain on his heart and found out impaired hearts whether they had a detectable lesion or not During and after the American Civil War it was shown that there was a form of heart trouble to which soldiers were particularly liable—namely, that which was known as "irritable heart." Shortly after the outbreak of the present war soldiers who had been invalided because of heart trouble began to consult him, and at the later stages of the conflict they had appeared in increased numbers When he was asked to take charge of the inquiry into disorders of the heart for the Medical History of the War he had an object in view which would give their researches a profitable aim. Dr R. M Wilson and he had examined 400 cases In 90 per cent. of the cases which had been certified as having heart affections they were found not to be primarily heart cases, so that the principles of treatment applicable to those cases differed widely from those appropriate to real heart failure. There was a good deal of variation in their appearance and symptoms, but they were usually spare, with drawn faces, and showed great vaso-motor instability Sometimes the hands and fingers became pale, while at other times they were thick and red, and the nose became red, sometimes even blue on slight exposure to cold Even after treatment by rest and feeding they were pasty faced and cold and seemed to be scant of breath Asked how they felt a common reply was "Rotten!", they easily became exhausted were breathless on moderate exertion, and frequently there was pain in the region of the heart. Often the frequency of the heart beat was not increased but in some it maintained a rate of *120* per minute. Exercise might cause undue rapidity, and it was in consequence of this excitability that the term "irritable heart had been used A slight increase in the size of the heart was no uncommon in this condition, in acute cases there was some œdema of the legs The mental condition of these patients also varied, depression was not infrequent and often they became generally irritable and restless Some that consequently if the vaccine is given intravenously the production of immunity is more rapid and greater

During the past few years I have given patients on many occasions subcutaneous injections of Friedländer vaccine with no visible beneficial effect, but since I have given the vaccine intravenously I have found great benefit produced Instead of a Friedländer infection being a most refractory one to treat, I find it to respond at once In some cases after a course of treatment it may be difficult or impossible to get a culture of the organism from the nose

It is for ozæna that I have used a Friedländer vaccine, but I would not like it to be gathered from the above that to give an intravenous injection of Friedländer vaccine is all that is necessary to do to alleviate patients suffering from this disease

A CASE OF GENERAL TETANUS FOLLOWING LOCAL TETANIC SPASMS OF INJURED LIMB

BY THOMAS B MOUAT, M D EDIN , F R C S ENG ,
CAPTAIN R.A.M C (T) 3RD NORTHERN GENERAL HOSPITAL, SHEFFIELD HONORARY ASSISTANT SURGEON ROYAL INFIRMARY SHEFFIELD

ON Sept 25th, 1915, the patient (a private in the Black Watch, aged 40) was wounded by a fragment of shell, which caused an extensive lacerated wound of the left upper arm, with compound comminuted fracture of the left humerus A field dressing was applied and tightly bandaged on, to arrest the hæmorrhage from the wound Fourteen hours after being wounded he reached a field ambulance at La Gorgue, where he was given an anæsthetic, the wound was cleaned and dressed, and antitetanic serum was administered subcutaneously He was then sent down to Boulogne, where he remained from Sept 27th to Oct 12th, when he was transferred to the 3rd Northern General Hospital, Sheffield

On admission, on Oct 13th, there was a large and deep lacerated wound on the posterior aspect of the left upper arm, with extensive loss of substance of the triceps muscle The middle portion of the shaft of the humerus was comminuted and necrosed fragments had apparently been removed, as there was a gap of over an inch between the broken up ends of the bone in the base of the wound The musculo spiral nerve was completely divided, and the muscles supplied by it and by the median nerve gave the reaction of degeneration The wound was septic and covered with unhealthy granulation tissue

From the date of admission—Oct 13th—up to Nov 5th, when the limb was amputated, the patient complained of painful spasms in the injured limb These spasms of the muscles of the injured limb were noticed from time to time and they were usually excited by the dressing of the wound A circular amputation was performed on Nov 5th The line of amputation was carried across the wound, which was now apparently clean and covered with healthy granulations The nerves cut across were swollen and œdematous looking, and stood out in a striking manner on the face of the stump —they were pulled down and cut off short

On Nov 7th (two days after amputation) the muscular twitching, which had recommenced in the muscles of the stump, spread gradually to the muscles of the shoulder girdle The patient began to look distressed, was grey looking, and sweating freely The condition was thought to be due to an ascending neuritis, as the muscular twitching before operation had been also ascribed to this On the 8th the flaps of the stump were opened up freely, and the wound showed signs of local infection On the 11th the spasms spread to the shoulder girdle muscles of the opposite side Two hours later the patient developed trismus and head retraction The appearance and symptoms had now become those of an ordinary case of tetanus, with the exception that the spasms were still most marked in the muscles of the shoulder girdle of the injured limb and especially in the pectoral muscles of that side 3000 U S units of antitetanic serum were given intrathecally, after allowing the escape of a similar amount of cerebro spinal fluid, 1500 units were also injected into or about the upper cords of the brachial plexus on the left side Chloral hydrate in 15 grain doses was given four hourly by the mouth On Nov 13th the patient had got steadily worse and was in a very serious condition The general muscular spasms were intense and frequent, and he was unable to take nourishment or to retain nutrient enemata 6000 units of antitetanic serum were injected intrathecally, and apparently with distinct benefit to the patient Gradual improvement set in The septic condition of the amputation stump cleared up and the wound healed The muscular spasms gradually became less severe and less frequent, and ceased completely about Nov 20th The patient now appeared to be convalescent, but in the first week of December he developed a right sided subdiaphragmatic abscess, possibly of pyæmic origin This was opened and drained on Dec 6th The patient died, apparently as a result of this complication, on Dec 30th

The points which appear to be of interest and the conclusions which might be drawn from the above case are as follows —

1 The onset and persistence of the tetanic spasms in the injured limb Several similar cases have been recorded recently[1] In all these it is definitely stated that the patient had received a prophylactic injection of tetanus antitoxin The unusual mode of onset and progress of these cases is apparently due to the fact that a certain amount of central resistance to the spread of the toxin had been set up by the prophylactic injection of tetanus antitoxin A sufficient interval had, however, elapsed before its administration to permit of a local spread of the toxin into the efferent nerves of the injured limb, which caused the onset and persistence of the local symptoms

2 The further absorption or spread of the toxin which followed the operative traumatism of the injured area was sufficient to overcome the increased general resistance which had resulted from the prophylactic injection

3 Definite amelioration of the symptoms followed the intrathecal injection of a large dose of tetanus antitoxin, 6000 U S units, whereas a dose of half that amount appeared to have little effect

---

Discussion on "Soldier's Heart"

A MEETING of this section was held on Jan 18th, Lieutenant-Colonel W HALE WHITE, R A M C (T F), the President, being in the chair The subject under discussion was "Soldier's Heart "

SIR JAMES MACKENZIE, in opening the discussion, said it may well be recognised that the trying life to which a soldier was exposed placed a strain on his heart and found out impaired hearts, whether they had a detectable lesion or not During and after the American Civil War it was shown that there was a form of heart trouble to which soldiers were particularly liable—namely, that which was known as "irritable heart " Shortly after the outbreak of the present war, soldiers who had been invalided because of heart trouble began to consult him, and at the later stages of the conflict they had appeared in increased numbers When he was asked to take charge of the inquiry into disorders of the heart for the Medical History of the War he had an object in view which would give their researches a profitable aim Dr R M Wilson and he had examined 400 cases In 90 per cent of the cases which had been certified as having heart affections they were found not to be primarily heart cases, so that the principles of treatment applicable to those cases differed widely from those appropriate to real heart failure There was a good deal of variation in their appearance and symptoms, but they were usually spare, with drawn faces, and showed great vaso-motor instability Sometimes the hands and fingers became pale, while at other times they were thick and red , and the nose became red, sometimes even blue, on slight exposure to cold Even after treatment by rest and feeding they were pasty faced and cold and seemed to be scant of breath Asked how they felt, a common reply was "Rotten ! ", they easily became exhausted, were breathless on moderate exertion, and frequently there was pain in the region of the heart Often the frequency of the heart beat was not increased, but in some it maintained a rate of 120 per minute Exercise might cause undue rapidity, and it was in consequence of this excitability that the term "irritable heart' had been used A slight increase in the size of the heart was not uncommon in this condition , in acute cases there was some œdema of the legs The mental condition of these patients also varied, depression was not infrequent and often they became generally irritable and restless Some were content to lie in bed and brood over their woes A condition somewhat akin to this was found in people who were recovering from an exhausting illness, or who had had a severe surgical operation, or had endured prolonged and anxious labour with but little sleep In most of the cases of that kind in this war there was a history of an illness preceding the breakdown, they were in the trenches, and felt well until one day which they remembered They were found to have a raised temperature and were given a few days' leave but on returning they still felt far from well, and after a few weeks of hard trench life they collapsed Sometimes they had had diarrhœa, sometimes measles, but mostly the history pointed to a form of infection Many of the patients recognised the gradual onset of the trouble In some a history of infection could not be gleaned, but there had been a strenuous life He related the history of one case as an example, the patient —who had been operated upon for appendicitis—having been able to snatch only short periods of sleep in the day time, with none at night, for several consecutive days, resulting in a feeling of illness and pain over the heart Some who had never been to the front and had not experienced excessive bodily or mental strain had shown the same symptoms following some febrile affection The "soldier's heart" he considered to be a sign of general exhaustion, the circulatory symptoms being but part of the general manifestation These differed from the cases in which a disease-producing organism had invaded the heart itself In some cases there might be doubt as to whether the condition might not be due to infection of the heart itself Judgment must be deferred until the subsidence of the fever If the temperature persisted for some weeks and no source of infection could be found, then the idea of infection of the heart became strengthened In the poisoned heart the first sign was usually a sense of exhaustion often supposed to be a sign of cardiac inefficiency, but it owned a different mechanism People suffering from toxic influence had the central nervous system affected, as shown by a feeling of illness and depression and they had irritability of temper, vaso-motor disturbance, and extra susceptibility of the peripheral circulation Chilliness persisted after a cold bath, but at times heat flushings passed over the whole body There was also a feeling of discomfort, sometimes even of pain, over the heart The persistence of pain when the patient kept at rest he regarded as strongly suggestive of poisoning "Soldier's heart" was due to trouble in other systems as well as the cardiac, such as the central nervous system It was unfortunate that the regulations required that each sick soldier should be certified as suffering from a definite complaint, because the hurry of examination did not permit of a careful study of all the cases A recognition of the nature of the illness would at once suggest the appropriate treatment—e g, if microbial efforts would be made to increase the patient s resistance, if poison, attempts would be directed to eliminating the poison The mental condition must also be taken into consideration Too much rest in bed should be avoided for irritable hearts, the heart, like other organs, was benefited by judicious exercise The aim should be to help the body as a whole, and to this end the provision of enjoyable games did much the patient being enjoined not to continue after the interest flagged or he felt tired This advice was safe in all obscure or doubtful heart conditions. Grievous injury was sometimes done to the mind of the soldier who was told he was suffering from an affection of the heart which was of grave importance

Dr R M WILSON gave a historical review of the subject and expressed agreement with the conclusions of Sir James Mackenzie with whom he had been working

Dr F J POYNTON referred to the heart affections, such as pericarditis and endocarditis, produced experimentally from streptococci He did not think a heart which had once thoroughly broken down in training would ever be strong enough again to allow its possessor to be fit for military service The factor of infection at the present moment was of the highest importance owing to the prevalence of dysentery and other gastro-intestinal disorders In some cases of "soldier s heart" he thought the condition was due to the development of the heart not having kept pace with the rest of the body, hence it failed when strain was put upon it. He had never been able to regard the heart as quite dissociated from the general nervous system, and one day it might be recognised how important it was to safeguard tall strong youths in this regard, when steps would be taken to save them from early strain

Dr R W MICHELL spoke from personal experience of the conditions at the front, and related a number of examples of the condition under discussion which had come before him Various forms of irritability were seen, including the passing of large quantities of urine, as much as three quarts at a time He fully agreed with what had been said as to the influence of toxæmia

Dr PHILIP HAMILL expressed his agreement with the opener, and related a number of interesting cases He fully agreed that the psychical factor must be treated before recovery could be expected But, apart from the latter, his view was that the hearts of many of these cases were permanently damaged, and if particulars were carefully taken and the cases followed up, it would be for the next generation to draw conclusions as to the precise nature of the disorder

Dr FLORENCE STONEY (who has been working at Fulham Military Hospital) declared that irritable heart was only one symptom of Graves's disease, and that this condition of heart was not met with by itself Her method of treatment was to reduce the size of the thyroid gland, by means of X rays, to the desired extent, and so affect favourably the heart condition, and she had been engaged upon that method for eight years with encouraging results Exophthalmic goitre she regarded to be at the root of the whole affection

Dr BEZLY THORNE pleaded for the use of the Nauheim treatment in cases of "soldier s heart," as it had yielded him excellent results

Dr ALEXANDER MORISON and Dr T R BRADSHAW also spoke, and Sir JAMES MACKENZIE replied

---

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF MEDICINE

The Electrocardiograph —Cases connected with Liver and Biliary Passages

A MEETING of this section was held on Nov 12th Professor J A LINDSAY, the President being in the chair

The PRESIDENT read a paper, illustrated by diagrams, tracings, and a lantern demonstration, upon the use of the Electrocardiograph. He said that amongst the recent advances in medicine an important place must be assigned to the development of instrumental methods of observation in connexion with the heart in health and disease The polygraph and the electrocardiograph had opened up a new chapter in this field and had rendered many former observations more or less obsolete While too much importance could not be assigned to a careful observation of the whole clinical complex instrumental methods added new and important facts The phenomena of disease were thus presented at first hand, and the duty of the clinician was that of interpretation These methods were of special value in certain departments where the difficulties of diagnosis were formerly greatest, as for example in the differentiation of the cardiac arrhythmias, the detection of heart-block and of auricular fibrillation, and in general in the recognition of myocardial changes He briefly described the structure of the electrocardiograph and the methods of employing the instrument, as well as the electrical phenomena of the normal heart The chief applications of the instrument in disease were then dealt with, the following conditions being passed under review—viz. heart block auricular fibrillation auricular flutter, myocardial degeneration extrasystoles, and hypertrophy of the ventricles Electrocardiography was probably destined to throw light upon the action of drugs, especially that of the cardiac remedies of the digitalis group It could not be expected to throw direct light upon valvular lesions Its message was from the cardiac musculature, not from the cardiac valves None of the usual valvular lesions had a precisely distinctive cardiogram, though that of mitral stenosis could sometimes be recognised. Hence, a normal electrocardiogram was no guarantee of a normal heart But valvular lesions sooner or later produced muscle changes, and these wrote their story upon the cardiogram. In conclusion the speaker deprecated any exclusive reliance upon instrumental methods The final test of cardiac sufficiency or insufficiency must remain the appeal to experience and to clinical observation —Professor W H. THOMPSON referred *to the numerous difficulties* in *the employment* and interpretation of the method, but expressed his belief that time would elucidate the majority of these. He pointed out that while the P – R distance is important, the T wave is even more so as showing whether ventricular contractions were dropped or not A large amount of experimental work had been done in Belfast by Dr Gibson and Professor Milroy with particular *reference to this* T wave —Dr J LITTLE also spoke —The PRESIDENT, in replying said that practically all the tracings had been obtained in the Victoria Hospital Belfast Instrumental methods could never replace trained clinical observation, but they had one most important quality—namely the elimination of the personal factor

Sir JOHN MOORE reported on three cases of more than usual interest in the wards of the Meath Hospital, all connected with the liver and biliary passages, and illustrating the value of surgical help The first case was that of a time expired soldier, aged 27 years, who had served in India for six years In August 1914, he came back to France and was severely wounded three months later his right tibia being fractured. A year before he left India he apparently had suffered from amœbic dysentery Two months before admission to hospital he again suffered from pain in the right side, followed by vomiting and diarrhœa The liver was found to be enlarged and tender on pressure Mr H Stokes operated in the belief entertained by him and by the speaker that the man had hepatic abscess The liver was the seat of an acute inflammation but no pus was found. Marked improvement followed on the operation The medical treatment consisted in the hypodermic injection of emetine hydrochloride in full and repeated doses The man made an excellent recovery The other two cases were instances of biliary colic, relieved by operation. In the former the number of stones (92) was remarkable, in the latter case Mr R. Lane-Joynt on operating, found that the gall bladder was obliterated This was a complicated case from its nature and by the development of a duodenal fistula after the operation But in 10 days the patient began to amend—steady improvement set in ending in a full restoration to health Two stones of considerable size were extracted from the common bile-duct

WEST LONDON MEDICO-CHIRURGICAL SOCIETY —A clinical meeting was held in the society's rooms, West London Hospital on Jan 14th Dr Leonard C T Dobson the President, being in the chair —The following cases were shown —Dr F S Palmer 1 Functional Monoplegia due to shock from bursting shell, soldier aged 24 2 Complete Mutism and Deafness due to shock from bursting shell soldier aged 28 Steady and uninterrupted progress under a system of re-education, without hypnosis —Major W McAdam Eccles 1. Abnormal Venous Channel in a male patient dilatation of the anastomosis between the two superficial external pudic veins with imperfect descent of the left testis In reference to the case of caput Medusæ shown by him at the clinical meeting held on Nov 5th Major Eccles described the abnormal conditions revealed by laparotomy of some of the intra abdominal veins 2 Two cases of Femoral Hernia in Man —Mr O L Addison Malignant Glands of Neck, male, aged 60, almost total disappearance under massive doses of X rays heavily filtered for a period of about three months at the rate of two or three a week.—*Dr E. Arthur Saunders* 1 Severe Rickets and Tuberculosis, male 5 years 2. Subacute Rheumatism, multiple rheumatic nodules in occiput (temporal regions) knuckles elbows wrists ankles knees flexor tendons of wrists sternum scapulæ and vertebræ, male 11 years —Mr N Bishop Harman 1. Case showing the effects of Chronic Blepharitis said to have followed measles, male aged 32 This was described by Mr Harman as being one of the worst cases of chronic blepharitis which he had ever seen 2 *Iridodialysis* caused by air-gun injury female 10 years —Dr George Pernet 1 [illegible] of Trunk and Limbs, male 6 years 2 Morphœa Scleroderma, outer sides of legs, female, 14 years —The following skiagrams were shown by Dr Reginald Morton —Cases under the care of Dr Saunders 1 Absorption and Collapse of Fourth and Part of the Fifth Lumbar Vertebræ following paratyphoid fever, male, 30 years 2 Large Aneurysm of the Arch of the Aorta with protrusion of the sternum (two skiagrams) Cases under the care of Mr Addison 1. Myeloid Sarcoma of Upper Ends of Tibia and Fibula female, 43 years 2 Old case of Tuberculous Disease of the Hip-joint, male, 26 years 3 Large Branched Calculus in the Pelvis, and a Round Calculus in the Cortex of the Left Kidney, female, 36 years Case under the care of Mr H. S Souttar Tuberculous Disease of the Hip-joint with Dislocation, male, 8 years Case under the care of Mr H Tyrrell Gray Shrapnel Bullet in Side of Neck, which entered in the region of the scapula of the opposite side, male 30 years Case under the care of Mr E. D McDougal Shattering of Upper Part of Humerus by Shrapnel showing curious formation of new bone —The President, Major Eccles, Dr Saunders, Dr Seymour Taylor, Dr Harold H. Sanguinetti Mr Addison, Dr S D Clippingdale Mr Rowland Pollock and Dr Morton took part in the discussion on the various cases

Reviews and Notices of Books.

Veterinary Anæsthetics

By FREDERICK HOBDAY, F R C V S F R S E London Baillière, Tindall, and Cox 1915 Pp 86 Price 5*s* net

Professor Hobday, who is at present serving as a major in the Army Veterinary Corps in France, gives a useful account of anæsthetics and narcotics for animals and birds, studied especially from the point of view of the general veterinary practitioner Commencing with the selection and practical application of anæsthetics for the different species of animal patients which the veterinary surgeon of the present day is called upon to treat, particular attention is drawn to the precautions necessary to ensure the safety of the individual patient, and in this respect the veterinary surgeon has many difficulties to contend with Only rarely can he obtain the assistance of a skilled anæsthetist, and thus be set free to attend exclusively to his operative work Hence it is interesting to note to what use narcotics are put, and especially the use of morphia for operations on the dog, the peculiar idiosyncrasy of this animal for the drug rendering it a most apt subject Doses which would be fatal to a man of 10 or even 15 times the body-weight act merely as a narcotic in the dog, and are sufficiently deadening to pain to enable even very severe operations to be performed with safety On the horse and cat on the other hand, morphia has an excitant and delirant effect Horses and dogs, according to the author, take chloroform very well, and numerous illustrations are given of apparatus and inhalers used for dosimetric administration. By these, according to statistics given, the proportion of chloroform to air can be regulated to a nicety, and several of them we recognise as having been brought before the members of the Anæsthetics Section of the Royal Society of Medicine, and the recent International Congress of Medicine The general anæsthetisation of the bird, especially the ostrich and the common fowl, is fully dealt with, chloroform being again preferred The chapters on local anæsthesia deal with all the local anæsthetics in general use and mention the precise limit of dose which can be employed with safety The final chapter is devoted to the intraspinal method

LIBRARY TABLE.

Medicine and Meditation Occasional Writings by Alex Lewers, L R C P Lond, D P.H Lond, Senior Honorary Physician to St Vincent's Hospital, Melbourne, and Lecturer on Clinical Medicine, St Vincent's Medical School Melbourne Ford and Son 1915 Pp 127—In this little volume 57 short articles of medical interest which have already been published in various journals are collected together by the author They cover a wide range of topics, for they deal with euthanasia, electricity, drink cures, syphilis, phrenology, and eugenics—to mention a few of the subjects taken at random, while matters which are likely to receive increased attention in the future, such as physical culture, school cooking, and the inspection of school children, are also included Dr Lewers has a plain straightforward style, and as a general rule his judgments are marked by breadth of view and proper caution Sometimes the fact that his judgment is based on the consideration of circumstances as they occur on the other side of the globe obtrudes itself abruptly For example, he makes the sweeping statement that "the consumptive of to day is viewed with as much popular distrust as the leper of the Middle Ages, and the still growing dread is not lessened by the fact that the results of treatment have not shown that any more definite control of the disease has been established" Surely in England, at any rate, the public know now that much phthisis not only can be, but is being prevented With regard to the statement that Shakespeare's recognition of genius as a physiological abnormality led him "to remark on the near alliance between madness and great wit," we think this is an old slip Anyhow, the familiar line, "Great wits are sure to madness near allied," occurs in *Absalom and Achitophel* and not in *Hamlet*, though Shakespeare's tragedy is often searched for the quotation Dr Lewers has provided us with a very readable and useful little volume

Japan By Pierre Loti Translated from the French by Laura Ensor Pp 334 Price 7*s* 6*d* *Jerusalem* By Pierre Loti Translated from the French by W P Baines Pp 212 Price 7*s* 6*d* net London T Werner Laurie 1915—These translations of two well known works of the distinguished French sailor who writes under the pseudonym of Pierre Loti are part of a series of his works which is being published in English guise with appropriate illustrations The work entitled "Japan" is, of course, a translation of the well known romance "Madame Chrysanthème," which profoundly amused and somewhat scandalised literary circles more than a quarter of a century ago The story has in its English form more of the delicate charm of the original than might have been expected, and this is assisted by profuse illustrations by Rossi and Myrbach, which have caught the very spirit of the author Some day or other, no doubt, Admiral Viaud s book will form an interesting historical note, so enormously does the Japan of to day differ from the Japan where he spent that long ago summer, and where the episode occurred round which the story is grouped

"Jerusalem is a literary and poetical guide book, and the same difficulties do not arise in its translation which must have beset the translator of "Japan.' Pierre Loti s book on the cradle of Christianity claims only to be a description of its present day ruins and desolation, and of the influence of the sacred place on a convinced unbeliever The religious musings and emotions have not the ring of actuality, while the verbal pictures show Pierre Loti to have revelled in the scene But it is curious to be reading a description of the old city as derelict and no longer of any account save as a centre of pious pilgrimages at the time when we hear of it in the journals as an important station on the Turkish lines of communication or advance Anything like desertion must be at complete variance with its present aspect

We recommend both these translations to our readers very sincerely Pierre Loti is a great man of letters, and the poetry and charm of his writings come out in the English version to an extent which we think will be a little surprising to those who have read his books in the original We wonder whether altered circumstances have changed his views of the English

JOURNALS

The Indian Journal of Medical Research Vol III, No 2.—The first contribution to this number is by Lieutenant Colonel W D Sutherland, I M S, Imperial serologist, Calcutta, and is in the form of a note on 2643 medico-legal cases, in which 6566 articles suspected to be blood stained were examined during a period of 31 months Of the 2643 cases in question 1650 related to charges of murder, 101 to culpable homicide, 87 to attempted murder, 284 to assault, and 189 to rape Of the total 6566 suspected articles submitted for examination 1380 were found to be free from blood Colonel Sutherland remarks that the wiles of the Indian criminal, his friends and his representatives, the intense longing that is felt by many a villager to get his enemy into trouble at whatever cost, the ingenious attempts of the unchaste village maid to pose as the victim of a brutal and lustful man, may all be gathered from the summaries of some of the cases that have come under notice—Major S R Christophers, I M S, and Dr K R K Iyengar discuss in a joint paper the effect of hæmolytic drugs, toxins, and antisera upon the hæmolytic point (so-called isotonic point) and the association between this point and hæmoglobinuria Major Christophers also furnishes two other articles—one on the pilotaxy of anopheles and the other on the male genitalia of anopheles, illustrated by plates—Some notes on Sumatrian culicidæ are contributed by Dr A. T Stanton bacteriologist of the Institute for Medical Research Federated Malay States and in continuation of his special studies on cholera Major E D W Greig I M S gives an account of some experiments he made on the production of gall stones in rabbits following intravenous inoculations of cholera like vibrios isolated from the stools of cholera patients and from water—Major A G McKendrick I M S, director of the Pasteur Institute of India, Kasauli supplies two articles the first dealing with the epidemiological significance of repeated infections and relapses and the second with the epidemiological significance of splenic enlargement in malaria.—Another instalment of their special studies on the treatment of snake bite is contributed by Captain Hugh W Acton I M S and Captain R Knowles I M S and this deals with the present position of antivenene therapy These experts express the opinion that with the remedies at present available for the treatment of bites from poisonous snakes if properly applied it should be possible to save a large percentage of the cases which now prove fatal The general lines of procedure recommended by them are (1) to apply a firm ligature immediately, (2) to impregnate the whole area of the bite with a hypodermic injection of a strong solution of gold chloride, and (3) to inject from 100 to 200 c.c of antivenene intravenously, if the biting snake be suspected to have been a cobra or Russell s viper If symptoms of venom intoxication come on further and even larger injections of antivenene should be given intravenously With sera concentrated ten times a dose of 20 to 60 c c should save every case of cobra bite—The last paper in this number of the journal is a short one by Mr J L Mitter entomological assistant at the Central Research Institute Kasauli on the occurrence of Stegomyia maculosa at Kasauli and its breeding place

ROYAL MEDICAL BENEVOLENT FUND

AT a meeting of the committee held on Dec 14th, 1915, 46 cases were considered and £448 granted to 40 of the applicants The following is a summary of the cases relieved —

Widow aged 41 of L.R C P Edin who practised at Edmonton and died in 1910 At husband's death applicant was left practically unprovided for with two children now aged 8 and 10 years Has managed to earn a living until the war commenced by literary work Has friends in Los Angelos who recommend her to go there as the prospects look good for herself and children Help required towards her passage &c The Fund granted £20 and the Guild also provided clothes. The Professional Classes War Relief Council coöperated with the Fund and made a grant of £10 —Daughter aged 27 of L.R C.P Irel who practised in Ireland and died in 1895 Applicant's health was undermined through the long nursing of her mother who has recently died The Fund made a small grant a little time ago to enable her to take a short holiday A further grant of £2 was made —Widow aged 45 of M R C S Eng who practised at Gravesend and died in January 1915 Applicant was left with three daughters ages 13 to 21 and one son, aged 20 who is abroad and whose health is broken down. Applicant required a little help towards the education of the daughters to earn their own living Owing to the war it was impossible to sell the practice to advantage at present Applicant voted £10 and the case referred to the Guild with a view of helping with the education of the girls —Daughters (aged 62, and twins 45) of M D Edin who practised in London and died in 1873 Applicants immediate trouble caused by the death of mother who had a life interest in some property They endeavour to make a living by taking in paying guests and doing needlework but have not been very successful of late Voted £10 and referred to the Guild —Daughter aged 44 of M.R C S Eng who practised in South Wales and died in 1872. For many years managed to earn a living as a laundress, but recently has developed cancer which has quite incapacitated her from working Voted £12 in 12 instalments and referred to the Guild.—Widow aged 45 of M R C S Eng who practised at Beccles, where he had only recently established himself and died in January 1915 Applicant is trying to earn a living by taking in paying guests but owing to some extent to her house being near the East Coast she has not been very successful but has prospects of improvement. Voted £10 —Daughter aged 58 of M D Dub who practised in the Isle of Man and died in 1882. Applicant's money was badly invested and she lost all She is now an invalid suffering from rheumatoid arthritis Highly recommended by the Liverpool Branch of the Guild Voted £5 to the applicant through the Liverpool Branch of the Guild —Daughter aged 49 of M D Lond who practised in London and India and died in 1873 Applicant was able to supplement an income of about £20 per annum by teaching French, but owing to ill health is unable to continue this work Relieved twice £10 Voted £10 in two instalments —Widow aged 51 of M D Dub who was in the Royal Army Medical Corps and died in 1905 Applicant lives in a flat rent free and has a small army pension In addition to her four daughters ages 21 to 26 she has her mother partly dependent on her None of the daughters are strong nor have they been trained for work. They have recently been training for nurses Voted £5 and referred to the Guild —Daughter aged 55, of L.R.C S & P Glasg who practised at Glasgow and died in 1883 Applicant managed to earn a living before the war by teaching music, but since October 1914 has practically lost all her pupils Only permanent income £4 12s per annum and lives in own house. Voted £12 in 12 instalments Recommended by the Glasgow Branch of the Guild —Daughters, ages 44 50 55 of M R C S Eng who practised at Bodmin and died in 1912. Until father's death they were all able to live comfortably together as father had a life interest in some property Only income of the daughters £5 each per annum Voted £18 in 12 instalments jointly and referred to the Guild —Widow aged 73, of M R C S Eng who practised at Rye and died in 1891 Applicant has cataract in both eyes and unsatisfactory health Has two daughters, both married. Lives in own house but has only very limited means Voted £12 in 12 instalments —Daughters ages 64 66 of M D Leyden who practised in London and died in 1858 Applicants only certain joint income £28 which they supplemented by taking in boarders Owing to the war the boarders have entirely ceased and they are in difficulties Helped by the Fund 21 years ago. Voted £12 and the elder sister recommended for an annuity —Widow aged 63 of M D Dub who practised at Cambridge and died in 1904 Applicant had managed to live by taking in resident pupils but owing to the war has practically lost them all Rent paid by relatives but now in temporary difficulties owing to the loss of above and illness Voted £10 and referred to two other organisations for help —Widow aged 58, of L.S A Lond who practised at Bournemouth and died in 1913 Applicant was left totally unprovided for Has a pension of £26 per annum from another society and during the last year has only received £5 from lodgers Health very unsatisfactory and unable to let more rooms Relieved once £12. Voted £12 in 12 instalments —Daughter aged 53, of M R C S Eng who practised in London and died in 1880 Applicant's health is very bad and she is quite unable to work Lives with a widowed sister who finds home but cannot do more Relieved six times £51 Voted £10 in two instalments —Daughter aged 58 of L R C P Lond who practised at Brierley Hill and died in 1872. Applicant suffers from chronic ill health and recently fractured her ankle Only income an annuity of £25 from another charity and a little help from friends Relieved eight times £53 Voted £12 in 12 instalments —Widow aged 54 of M R C S Eng who practised at Yelverton and died in 1903 Applicant endeavours to make a living by taking in boarders but does not get sufficient to make it pay Relieved nine times £107 Voted £12 in 12 instalments —Widow aged 42, of M R C S Eng who practised in North Wales and died in [illegible] Applicant was left quite unprovided for with two children now aged 6 and 9 years. Has free rooms in return for services and makes a little by selling goods on commission but not sufficient to meet expenses Relieved four times £[illegible] Voted £10 in two instalments —M R C S Eng L.R.C P Lond aged 49 who practised in Lancashire and abroad. Applicant is married with three children now aged 9 14 16 years and he has become totally blind Wife and children are cared for by relatives The applicant is now studying massage in London, and hopes shortly to be qualified and earn his living Only income £12 per year from a charity for the blind and a little from friends Relieved once £10 Voted £10 and referred to the Guild —Daughter aged 49, of M R C S Eng who practised at Gillingham and died in 1911, and was for some years an annuitant of the Fund Through ill health the applicant is not able to earn her living and receives her food in return for looking after a child during the day Has to pay rent for her room Relieved twice £17 Voted £12 in 12 instalments through the Guild —Widow aged 64 of M B Glasg who practised in South Wales and died in 1913 Applicant's only income £16 per year and her three children all married with families unable to help Health very bad Relieved three times £24 Voted £12 in 12 instalments.—Daughter aged 56 of M R C S Eng who practised at Rotherhithe and died in 1879 Applicant is suffering from chronic glaucoma, which prevents her from working as a nurse Only income from investments and friends £24 per year Relieved seven times £67 Voted £12 in 12 instalments —Widow aged 59 of L R C S Edin who practised on the West Coast of Africa and died in 1907 Applicant has two sons who are abroad and unable to help and one daughter aged 36, who is an invalid lives with her mother Applicant has recently broken her ankle and is incapacitated from doing any work Only income a little occasional help from friends Relieved four times £48. Voted £12 in 12 instalments —L.R C.P Edin aged 58, who practised at Old Kilpatrick N B is suffering from spastic paralysis Lives with a sister who has to earn a living by taking in boarders Only income is that given by the Fund Has one son aged 19 who is studying for a dentist and his fees being paid by the Fund and Guild. Relieved 11 times £132 Voted £12 in 12 instalments —Widow aged 56 of L S A Lond who practised at Islington and died in 1905 Applicant was left with two sons who helped to keep her The elder one however died in March 1915 and the other joined the army and has been missing since April 1915 She is now keeping house for two young nephews Relieved eight times £128 Voted £18 in 12 instalments.—Daughter aged 47 of M D Edin who practised at Southampton and died in 1886 Applicant's only income is £25 per annum from a charity and friends and is suffering from chronic neuritis and quite unable to continue her work as a nurse. Relieved twice £14 Voted £12 in 12 instalments —Daughter aged 71 of M.D Edin who practised in Somersetshire Applicant lost all her income through unfortunate investments Used to earn a little by painting but cannot obtain any commission at present. Relieved three times £42. Voted £3 and referred to the Guild for report —Widow aged 66, of L R C P Edin, who practised at Port Carlisle and died in 1893 Applicant was left quite unprovided for with five children none of whom are able to help Has recently had breast removed for cancer and otherwise health very bad Elected to an annuity of £10 by another charity this year Relieved twice £24 Voted £12 in 12 instalments —Widow aged 60 of M R C S Eng who practised in Liverpool and died in 1895 Applicant is a trained nurse, but in consequence of ill health is not always able to work. Relieved six times £42. Voted £12 in 12 instalments —Daughter aged 57 of M.R C S Eng who practised at Hammersmith and died in 1908 Owing to ill health the applicant is unable to obtain employment. Has no income but receives occasional gifts of clothes and food from friends, and help from the Guild Relieved eight times £104 Voted £18 in 12 instalments —Widow aged 54 of M R C S Eng who practised in Wiltshire and Devonshire and died in 1914 Applicant was left unprovided for at husband's death who was an annuitant of the Fund Receives a little help from friends but not sufficient to keep her and unable to obtain suitable work Relieved three times £16 Voted £12 in 12 instalments —Widow aged 56 of L.S A. Lond who practised at Limehouse E and died in 1894 Applicant was left unprovided for with two daughters now aged 21 and 23 years but neither living with their mother or able to help much Applicant's health very indifferent and only able to earn a little by needlework. Relieved 10 times £58 Voted £12 in 12 instalments —Widow aged 48, of M R.C S Eng who practised at Hexham and in London and died in 1903 Applicant dependent on boarders which is very precarious and what she can obtain by needlework. Has four step-children and one daughter of her own who lives with her but earns very little in consequence of bad sight Relieved six times £72. Voted £12 in 12 instalments and referred to the Guild —Daughter, aged 69 of M R C S Eng who practised at Cheltenham and died in 1879 Applicant's health was very bad suffering from rheumatism and defective sight Only income, two small annuities and not quite sufficient to live upon Relieved twice £24 Voted £12 in 12 instalments —Widow aged 61 of L R C P Edin who practised in Dublin and died in 1900 Was left unprovided for but was helped a little by son who has recently died Also earns a little by needlework Health now very indifferent Relieved three times £30 Voted £10 in two instalments.—Daughter aged 69 of M R C S Eng who practised in London and died in 1875 For 40 years earned her living as a governess mainly abroad and for the last ten years in Russia, and her life's savings were in a bank in Berlin and she has not been able to obtain any of them Has recently been able to earn a little by sewing but not enough to live upon Relieved once £12. Voted £12 in 12 instalments and referred to the Guild —Daughter aged 60 of M R C S Eng who practised in London and died in 1877 Applicant's only certain income a small pension from another charity Before the war she earned a little by teaching music Health has been very unsatisfactory of late. Relieved once £10 Voted £10

The claims on the Fund show a constant increase month by month At the last meeting the Committee had a record number of applications and only a balance of £42 to meet them with Grants were made to the extent of £448 To meet this deficit the reserves which had already been reduced by £500 will have to be further drawn upon Unless further support is quickly forthcoming the Committee will have no choice but to restrict its operations and that in the face of ever growing claims Subscriptions may be sent to Dr Samuel West, the honorary treasurer, at 11, Chandos street, Cavendish square, London, W

NATIONAL HEALTH INSURANCE

O Neill v Middlesex Insurance Committee

IN this action Dr B O Neill asked for an injunction to restrain the defendants from surcharging him £323 in respect of alleged excessive prescribing in his panel practice, and also for a declaration that the defendants were not entitled so to surcharge him, and that Regulations 40 and 51 of the Medical Benefit Regulations were *ultra vires* The surcharge was originally made upon a report of the Panel Committee and was adopted by the Insurance Committee upon the recommendation of a Subcommittee on March 1st, 1915 Shortly afterwards it had been found that the medical man had not been heard in his own defence by the Panel Committee, as he had a right to be, but had only been before a Subcommittee of the Panel Committee which had held the inquiry on behalf of that body In order to set this right the Insurance Committee sent the matter back to the Panel Committee for reconsideration and rescinded its own resolution of March 1st The Panel Committee invited the medical man to appear before it, and this he did but only under protest that the Regulations were illegal and *ultra vires*, and that any report or resolution of the Committee could not be enforced against him, and he refused to answer any questions or to offer any explanation The plaintiff s solicitors had already taken up on his behalf the position that the Insurance Committee had had the matter before it and was *functus officio* so far as any further consideration of it was concerned Mr Justice Rowlatt held as to this that the fact that the questions raised had been fully gone into already did not preclude the Committee from reopening them, and that the second meeting of the Panel Committee could not be called a pretence As the plaintiff had been invited to attend it and had refused to speak, it could not be said that he had not had a full opportunity to support his own case On the question whether Regulation 40 was *ultra vires*, his lordship referred to Section 65 of the Act of 1911, which gives the Commissioners power to make rules ' generally for carrying this part of the Act into effect." It was obvious, he considered that the Act did not give unfettered discretion to medical practitioners with regard to prescribing, and that there must be a limit to the amount available as well as a duty to prescribe reasonably In order to carry out the Act it was necessary to prevent extravagance in prescribing, and therefore the Regulation being made for this purpose came within the general powers given to the Commissioners for carrying the Act into effect He gave judgment for the defendant Committee with costs

Standing Orders for Panel Committees

The Insurance Commissioners have issued a set of draft standing orders for the assistance of Panel Committees The draft orders are described by the Commissioners as not necessarily exhaustive and as intended to be amplified or supplemented as may appear desirable. They seem, however, to cover most of the necessary ground, providing in the usual manner for the election of officers and defining their duties, with orders devoted to the procedure at meetings the procedure in connexion with cases of excessive prescribing, and other matters appropriate to the work of the committees in question

The Return of Record Cards

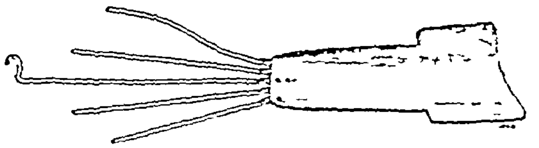
Medical men on the panels have been reminded by circular that the currency of the record cards prepared during 1915 expired on Dec. 31st, consequently the lower halves of such cards have to be sent to the Commissioners not later than Jan 22nd, and at the same time the upper halves to the Insurance Committee concerned. A good many instructions and warnings as to the making up and forwarding the records in question are contained in the circular and attention to these should insure accuracy, without which the machinery of the Insurance Acts cannot be expected to run smoothly

New Inventions.

A NEW METACARPAL SPLINT

OWING to the difficulty I have recently experienced in the treatment of fracture of metacarpal bones, I have devised a splint which provides both for the necessary abduction of the fingers and extension of the fragments, at the same time it allows a certain degree of mobility and leaves the hand accessible for passive movements and massage from the very beginning of treatment It consists of two portions—one for the forearm and the other for the carpus metacarpus and phalanges, the former is a shallow trough of galvanised iron shaped to accommodate the flexor aspect of the forearm, and the latter consists of five pieces of 3/16 inch copper wire arranged in such a way as to correspond to the five separated digits The wire half is fixed to the forearm portion by means of copper nails passed through the proximal ends of the digital wires and hammered out flat on the back of the distal end of the galvanised iron portion It will be noticed in the accompanying illustrations that the forearm portion has two lateral projections and the purpose of these is to give purchase to bandages which can be passed over them and above the elbow to provide for counter extension Extension on the distal fragment of the metacarpal bone is obtained by hooking a piece of rubber tubing attached to the finger or fingers over the extended portion of wire bent to a right angle and curved to accommodate the rubber tubing I have found that the most comfortable extension for attachment to the finger can be made by laying a piece of ¼ inch rubber tubing along the palmar and dorsal aspects of the finger and very lightly binding it in position with narrow adhesive plaster so that the bent loop of the rubber fits over the distal extremity of the finger, this loop of tubing can be stretched over the upturned end of the copper wire after the splint is bandaged to the forearm

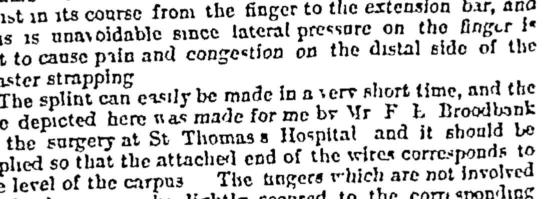
FIG 1



One seventh natural size

The illustrations for which I am indebted to Mr D C Bluett, show the splint as made for the treatment of fracture of the third metacarpal bone of the left hand, and the method by which extension is obtained It can, of course be applied with equal ease to more fingers and to the thumb It will be noticed that the rubber extension has a twist in its course from the finger to the extension bar, and this is unavoidable since lateral pressure on the finger is apt to cause pain and congestion on the distal side of the plaster strapping

FIG 2



One half natural size

The splint can easily be made in a very short time, and the one depicted here was made for me by Mr F L Broodbank of the surgery at St Thomas s Hospital and it should be applied so that the attached end of the wires corresponds to the level of the carpus The fingers which are not involved in the injury can be lightly secured to the corresponding wires by means of a rubber or metal ring or a turn of bandage

I have also used this splint with some success in the cases of cellulitis of the hand to prevent contraction of the fingers and for this purpose it may be made to apply to either the dorsal or palmar aspect of the forearm and hand With very slight modification it might be of value in the treatment of Colles s fracture

THE BURBERRY

THE WORLD OVER—discriminating medical men all agree that only ONE coat will stand the most critical test to which they can put it—

That COAT is THE BURBERRY

ITS SUCCESS has been phenomenal From friend to friend, by word of mouth, its value has been attested by thousands who appreciate its light weight, ease, weatherproofness, perfect self ventilating properties, its longevity, and its distinguished "hang" During 20 years it has been without a peer, though the air is now thick with imitations

But who wants an imitation when the real thing is available?

EVERY IDEA that tends to increase the comfort of the wearer is expressed in this coat. Nothing equals it, or can live with it for value, therefore, though offered you under the alluring banner of cheapness, reject all substitutes and imitations

If less in price, be assured the quality is degraded.

There is only ONE coat—THE BURBERRY—the Original—the Unequalled—the Dependable—the Incomparable

"SUPSALVS"

(REGISTERED)

STABLE SUPPOSITORIES, containing "606."

(Professor BAGROV'S Method)

At the International Congress of Medicine Ehrlich stated that the biochemical action of **"606"** on *spirochætes* is not direct but indirect, a third factor found in the body fluids being necessary

This success is explained by the well known experiment of Levaditi "If living treponemas be placed in a solution of Arsenobenzol (Ehrlich's 606) they continue to live in it But if a trace of extract of liver be added to the mixture the treponemas are destroyed "

"If 606 has to be taken up and transformed **by the liver** in order to become toxic to the treponema there is no better mode of absorption of the drug than **by way of the intestine,** since all the **veins of the intestines** join the **portal vein** If this be the case no route could be more indirect and more unsatisfactory for active treatment than one that is not intestinal or not intravenous (i e , prehepatic), since some of the drug must necessarily become fixed everywhere before the passage through the liver has activated it " — Dr Sabouraud, La Clinique (13-4-1913)

As a result of numerous clinical experiments, Dr Bagrov of Moscow, has arrived at the same conclusion, and recommends the rectal method of administration of 606

The rectal method of administration of 606 may be recommended to medical men who do not wish to employ intravenous injections It yields excellent results, absolutely comparable with those obtained by the intravenous method, and is free from all risk

In order to render the employment of suppositories containing 606 practicable, it was necessary to find some excipient that does not alter the active principle, even if kept for a long time, and that facilitates its absorption by the intestinal mucous membrane

This requirement has been realised in our **"Supsalvs "**

They consist of a nucleus containing the active principle and surrounded by a greenish and slightly aromatic external envelope

They contain no anæsthetic and do not react on the rectal mucous membrane

In arriving at our prescription we have selected an excipient that shall be capable of assuring the chemical stability of the 606 in the presence of the intestinal contents The active principle and the vehicle being bound to one another, the mucous membrane is able to absorb both simultaneously and progressively in the form of an organic emulsion

Within twelve hours after the administration of a suppository the blood and the urine contain the drug, and it is easy to detect the arsenic by analysis

Indications.

Specific affections in all stages Tertiary lesions (General Paralysis, Sclerosis Tabes)

Infantile Syphilitic Pemphigus

Malarial as well as Cancerous Cachexia, Trypanosomiasis, and, speaking generally, all diseases due to Treponema

Mode of Employment.

One **"Supsalvs"** every three days preferably after the bowel has been cleansed by an enema until six suppositories have been administered. Then an interval of a fortnight

The treatment is then repeated in the same manner until three series of six suppositories each have been employed. In acute cases one or two **"Supsalvs"** may be administered daily without any harm treatment being continued for a week

In Boxes of 6 " Supsalvs " (Adult)—dose 0 10 gr
" 6 " Supsalvs " (Infant)—dose 0 03 grm

N B —For **HOT CLIMATES** we deliver each " SUPSALVS " protected by a special *patented metallic envelope, consequently* our "SUPSALVS" may be kept any length of time without deterioration

In order to withdraw the suppository from its envelope, cut with a pair of scissors the projecting edge which occupies the middle part of the envelope (Fig 1) and then pull out the metal cups (Fig 2)

Before opening the envelope plunge it in fresh or iced water for ten minutes after which proceed as above directed.

THE LANCET.

LONDON SATURDAY JANUARY 22, 1916

The Supply of Medical Officers for the Army.

THE adequate supply of medical officers for the army still remains the most urgent professional question of the moment, and the Central Medical War Committee has decided to issue to every practitioner of military age a letter asking him to enrol with the Committee and to come up for service if and when required in the Royal Army Medical Corps or the Royal Navy Medical Service The letter is published on p 216 When the applicants for commissions have stated, on forms provided, their name, nationality, date of medical registration, and various particulars with regard to their previous employment, an authorisation to the Central Medical War Committee will enable that body to forward to the War Office the request for a temporary commission in the Royal Army Medical Corps or in the Royal Navy Medical Service, but the applicant will not be called up until, in the opinion of the Central Medical War Committee, the proper time has arrived, and of this one month's notice is promised

Doubts still remain in the minds of many of our readers—we know it from frequent communications not intended for public reading—which centre round these two questions 1 Is the civil population deprived of medical service to a dangerous point? 2 Has not the War Office obtained already a sufficient number of medical men for military purposes if a more economical use were made of the supply? With regard to the first question, we have dealt at some length with most of its aspects in recent issues of THE LANCET, but it is possible to speak a little more definitely than hitherto has been permissible We are glad to believe that the views of the public, of certain local authorities and of the managers of many charitable institutions have been unduly pessimistic A shortage of civil medical practitioners is unavoidable, and indeed has already occurred but the consequences can be guarded against The value of coöperation between the various public bodies concerned and of economy in the matter of medical service is beginning to be appreciated and the public will find that the present depletion of medical men which will *continue* for some time and will perhaps assume an exaggerated form, can be to some extent remedied by self sacrifice on their part That the National Health Insurance Commission should be working in harmony with the Central Medical War Committee [illegible] guarantee that no real disorganisation [illegible] place in the medical care of the public The Commissioners fully recognising [illegible] prepared analyses of the medical practitioners in England and Wales, which show the number of general practitioners and other medical men compared with population in each administrative area, and indicate clearly the places where a dangerous dearth of medical men might be found. The actual figures are, at the present moment at any rate, not for publication, but we may say that they have been arrived at with the exercise of every precaution. The practitioners are classified as general practitioners and "others," the latter term implying public officials, resident staffs of hospitals, consultants and specialists, retired practitioners, newly qualified practitioners and those whose practice appears to be purely dental All this information has been placed in the hands of the Central War Committee, which was already in possession of the intimate information concerning medical men in different localities of the country furnished by the British Medical Association. It will be seen, therefore, that the Central Medical War Committee is in a good position to come to a fair decision in making calls throughout England and Wales upon the various medical men whose applications for commissions reach them The calls of the Central Medical War Committee will be made presumably in *accordance* with the system of classification which has been published, but the circumstances of individual practitioners and the opinion of Local Medical War Committees will be taken into close consideration, and the value of such well informed inspection of the individual positions of practitioners will be understood

With regard to the second question, the War Office certainly requires more medical men with the army, but it is not possible for anyone to say exactly what the future demands may amount to, these must be regulated by military exigencies The number of medical men serving in the army makes it, of course, certain that from various causes there will be a definite wastage This wastage will increase, inasmuch as a very large number of commissions were granted after March, 1915, but there is a definite understanding that when the Army Medical Department needs more medical officers it will state the number required to the Central Medical War Committee, whose constitution and terms of reference have now been stated in the House of Commons Then there will fall upon that Committee the responsibility of assisting the Local Medical War Committees to a decision with regard to the calling up in particular localities of particular practitioners, but as it will be fully informed of the position by the National Health Insurance Commissioners also the difficulties and delicacies of making such decisions will greatly disappear It is hoped that medical men, under 45 when invited to enrol with the Committee will do so promptly for in this way the recruiting of medical men for the navy and army will remain in medical hands and the difficulties and inevitable injustices of general conscription may to a great extent be avoided

The Midwives Act for Scotland

THE Midwives (Scotland) Act follows in policy and outline the Midwives Act, 1902, which did not extend to Scotland or Ireland, but differs from it through the introduction of details some of which are of importance To the more prominent of these differences we call attention below The general policy is maintained of allowing women holding certain specified certificates in midwifery or who have been in practice as midwives to be certified (i e, enrolled) under the new law, of forbidding all others from using the title "midwife" or any other title implying certification, and of fixing a date (Jan 1st, 1922) after which no uncertified woman may practise as a midwife for gain In Section 1 (5) there is an addition qualifying the disability of a midwife as to the granting of certificates by permitting her to grant such as may be required in connexion with maternity benefit by Approved Societies or Insurance Committees In Section 2 the period of two years within which certification must be sought may be extended by the Central Midwives Board for Scotland to meet the exigencies of special cases of delay

The Board when fully constituted will consist of 12 members (Section 3), with power to seek certain modifications of its constitution, including increase or diminution of numbers, by representation to the Privy Council and with the consent of Parliament Of the 12 members mentioned, however, a group of three, who are to be appointed by the Lord President of the Council, will some day include two certified midwives practising in Scotland, "when midwives so qualified are available in sufficient number to warrant such appointment" The number of registered medical practitioners on the Board is fixed at five These are to be appointed one by the University Courts of Edinburgh and St Andrews, conjointly, one by the University Courts of Glasgow and Aberdeen, conjointly, one by the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow, conjointly, and two by the Scottish Committee of the British Medical Association One member of the Board is to be appointed by the Society of Medical Officers of Health of Scotland, who presumably will be a medical practitioner, so that there should be six medical men on the Board, two midwives, and four others who may, or may not, be medical practitioners The appointers of these four will be the Lord President of the Council (one), the Association of County Councils for Scotland (one), the Convention of the Royal Burghs of Scotland (one), the Queen Victoria Jubilee Institute for Nurses (Scottish Branch) (one) Meetings of the Board will be held at Edinburgh, reasonable expenses in respect of attendance being paid Section 5, defining the duties and powers of the Board, provides that it shall appoint examiners, one of whom shall be a registered female medical practitioner and none of whom shall be a member of the Board, the Act of 1902 only stating that the Board is to appoint examiners Section 5 contains another innovation in the term used to describe the functions of the medical practitioner who is to be summoned when in cases of special difficulty it is clear that the midwife should not deal with the case alone It will be remembered that by the Act of 1902 and the Regulations framed under it, in cases specified a midwife is to advise that a medical practitioner be sent for, ceasing to treat the case herself, and that no provision is made for the payment of the medical man, who may or may not be called in by those who receive the advice to do so In the Scottish Act the Board have the duty of (Section 5 (1) (e)) "regulating, supervising, and restricting within due limits the practice of midwives and defining the emergencies in which a midwife shall call in a registered medical practitioner to her assistance" From this it will be seen that the midwife is made directly responsible for obtaining medical help for herself in the performance of her duties, and we quote the section in which the duty is amplified —

> Section 22 (1) In case of an emergency as defined in the rules framed under Section 5 (1) (e) of this Act a midwife shall call in to her assistance a registered medical practitioner, and the local supervising authority shall pay to such medical practitioner a sufficient fee, with due allowance for mileage, according to a scale to be fixed by the Local Government Board for Scotland, and such fee shall cover one subsequent visit (2) It shall be a condition of the payment of such fee that the medical practitioner so called in shall state in his claim to the local supervising authority the nature of the emergency (3) The midwife shall report forthwith to the local supervising authority each case of emergency in which she has called in a registered medical practitioner to her assistance stating the nature of the emergency and the name of the medical practitioner (4) The local supervising authority shall have power to recover the fee from the husband or guardian of the patient as an alimentary debt, unless it be shown to their satisfaction that such husband or guardian is unable by reason of poverty to pay such fee

It will be observed that apparently it is the fee only and not the mileage which the local authority may recover It is hardly necessary to say how much friction in the working of the Act of 1902 might have been saved if this section had been inserted in, or promptly added to, that statute

Other features of the Scottish Act are as follows —Power is given to suspend as an alternative to removal from the roll of midwives, and to pay compensation where suspension has been followed by a decision in the midwife's favour, or has been imposed in order to prevent infection, provision is made for the reciprocal treatment of midwives certified in other parts of His Majesty's Dominions for the disposal of fees payable for examination or certificate, and for the audit of the Board's accounts, and there is a power of entry for officers of local supervising authorities to premises believed to be lying in homes, where it is believed that a certified midwife practises or that a woman not certified practises in contravention of the Act It is also ordered that the medical officer of every local supervising authority shall report annually to the authority on the administration of the Act, transmitting a copy of his report to the Board and to the Local Government Board for Scotland, and the Board is to present a report of its proceedings annually to the Privy Council The Midwives (Scotland) Act, 1915, came into force on Jan 1st, 1916

Annotations

"Ne quid nimis"

THE HEALTH OF MUNITION WORKERS

Memorandum No 2, submitted by the Health of Munitions Workers Committee to the Minister of Munitions, deals with those matters outside the ordinary undertakings of factory management which have to be considered if the full efficiency of any factory is to be maintained, and which present difficulties not easily to be overcome in connexion with the vast and rapidly organised munition works now being carried on The four chief influences affecting industrial efficiency to which the memorandum calls attention are those which raise questions of housing, transit, canteen provision, and the individual welfare of the employee The sudden influx of workers in certain districts has overtaxed housing conditions beyond any limits that would be tolerated in normal conditions of peace Railways and other means of transit in many cases cannot provide for the men and women to be carried without imposing upon them overcrowding, waiting delay and loss of time the provision of suitable food in the factories or in such lodgings as are available for the workers, is only arranged with difficulty and not always with satisfactory results, and those responsible for the organisation of the factories, as such, have their time fully occupied without being able to devote any appreciable part of it to the personal supervision of the individual welfare of their workpeople To secure improvement in these four important particulars is quite essential if the factory is to be maintained at its highest efficiency, for the good health and content of the workers are necessary to this end In order to obtain better conditions the recommendation made by the Committee is that 'welfare supervision' should be established by those responsible, such as is now receiving the attention of the more enlightened employers welfare supervision not being a new thing but one the usefulness and desirableness of which have suddenly been rendered conspicuous The task of the welfare worker is no light one requiring as it does experience if persons so endowed are obtainable but in any case tact good sense understanding of industrial conditions, and sympathy The memorandum refers to courses of social study as established at the University of London and the University of Birmingham comprising lectures and practical work and designed for persons seeking to qualify themselves for posts as welfare workers as well as for other similar employment Assuredly the recommendations of the Committee should secure the support of all who can help to render them effective and there should be educated men and women of good standing who in this great national emergency will find in work among munition workers fit scope for their energies and their patriotism. No doubt the need for women welfare workers to help where women and girls are employed is the more urgently and generally felt, but the need exists also where the munition workers are men, and particularly where they are boys For this reason the memorandum to which we have referred should provide interesting and suggestive reading for many who are anxious to help their country, but who as yet have not found the niche best suited to them. The Committee responsible for it, having Sir George Newman as its chairman, includes Sir Thomas Barlow, Bart, Mr G Bellhouse (of the Factory Department, Home Office), Professor A. E. Boycott, Mr J R Clynes, Dr E L Collis (Factory Department, Home Office), Dr W M Fletcher, Professor Leonard E Hill, Mr S Osborn (Sheffield), Miss R E Squire (Factory Department, Home Office), and Mrs H. J Tennant

"SOLDIER'S HEART"

IN opening the discussion on the soldier's heart at the Section of Therapeutics of the Royal Society of Medicine on Tuesday evening, Sir James Mackenzie dealt with a subject which he has made peculiarly his own, and compressed into a brief half hour a complete account of the subject from a clinical and etiological standpoint The condition known as "soldier's heart" is best defined by stating what it is not The life of the trenches is in every way a trying one for the soldier, it finds out his point of least resistance, which may be an impaired heart serviceable enough for the conditions of his every day life but unequal to any severe and prolonged strain Loss of compensation follows and the ordinary symptoms of heart failure But this is not the subject of Sir James Mackenzie's address "Soldier's heart" itself is something quite different, and was first clearly described by American physicians during the Civil War as a form of heart trouble to which soldiers were particularly liable It is a condition characterised by exhaustion of the circulatory system, shown as regards the heart by breathlessness, a sense of suffocation and præcordial discomfort, and a frequency which if not raised during rest becomes unduly increased on slight exertion As regards the vessels, the condition is marked by great vaso motor instability, shown in pallor or flushing of the nose and extremities, attended with giddiness or fainting in the more severe forms But the symptoms are not confined to the circulatory system and in 90 per cent at least of the cases observed this system is not the one primarily affected, the circulatory symptoms are part of a general illness in which the central nervous system has a large share. Apart from the vaso motor disturbances there is an irritability of temper a depression of spirits, an inability to concentrate thought, a nervous tension liable to lead to sudden outburst and a tendency to focus the attention constantly on the condition of the heart, which implies a profound influence on the nervous tissues The condition is reminiscent, indeed of another condition of nervous exhaustion which has already been described in these columns when dealing with special hospitals for officers with nervous exhaustion In both class of cases there is a marked disinclination for mental exertion. And there is thus in common to the two states both are generally the sequel of prolonged strain combined with long periods of sleeplessness, with a severe shock, such as may follow the bursting of a high explosive shell, as the immediate forerunner Both, too, when fully developed are attended with much mental distress, which persists for a long time and passes off again very slowly In the one case the nervous system is probably itself the point of least resistance, in the other the circulatory system has also suffered, whether from the toxic influence of some infection or more directly from strain in the adolescent period, and the great majority of these cases occur in quite young soldiers who have not yet completed their full stature or full internal development The toxic influence, although not proved as an etiological factor in all cases, has much to answer for, as in a majority of cases there is a history of a period of malaise with slight febrile movement, insufficient, it may be, to occasion invaliding, succeeded after an interval by a second attack of a definitely incapacitating nature Upon most of these etiological points Sir James Mackenzie touched, but he was careful not to attach any degree of finality to them His desire is to continue the study of these cases, on a large scale, in a special hospital where accurate diagnosis and classification would be possible Treatment must follow on rational lines, and where a toxic origin has been established, it must include an attempt to brace up the powers of resistance, to eliminate the toxic products, and to renew the tissues specially affected One of Sir James Mackenzie's opinions deserves wide attention Where the condition is one of simple "soldier's heart," absolute rest is not indicated, rest in bed may tend merely to further weaken the cardiac muscle Appropriate and not excessive exercise is the right treatment both for the heart and the depression of spirits, and may take the form of fishing, riding, and golf for the officers, and suitable games such as bowls, quoits, and skittles for the men Sir James Mackenzie holds that in the indulgence in exercise, as long as it produces pleasurable feeling and no discomfort, lies the whole philosophy of the therapeutic treatment as far as the heart is concerned

CASES IN WHICH A POSITIVE WASSERMANN REACTION WAS OBTAINED IN PATIENTS LATER AFFECTED WITH SYPHILIS

POSITIVE Wassermann reactions are regularly found, not only in syphilis, but in some other protozoal diseases A positive result is also met with from time to time in patients who are affected with other diseases, but in all of these latter cases the question must arise, Have these patients been affected with syphilis previously so that the positive reaction is due to the syphilis and not to the other condition from which the patient happens to be suffering at the moment? Now it is exceedingly difficult to prove that a patient has not had syphilis, but it occurred to Dr S A Volyansky that as infection with syphilis is a perfect proof that at the time of infection the patient was not affected with syphilis it might be profitable to trace the subsequent history of these cases with positive Wassermann reactions to see if any of them later became affected with syphilis Dr Volyansky has made notes of a number of cases in the Kalinkinsk Hospital, Petrograd, in whom a positive Wassermann reaction was obtained without there being anything in the history or the symptoms to suggest a syphilitic taint, and certain of these cases were admitted some months later with primary sores, so that it may be fairly safely assumed that at the time when they gave positive Wassermann reactions they were not affected with syphilis In a paper which he has contributed to the Russian *Vrach* he gives details of two of these cases In one of them, a young woman, who was admitted with scabies, had some indefinite ulceration on the labium minus A well marked positive Wassermann reaction was obtained The patient was treated but without mercury, and she was discharged in a little less than three weeks Two months later she was admitted with a soft chancre, but eight months later she was again admitted with a hard sore and a syphilitic eruption In the other case the patient was first admitted with gonorrhœa and a well marked positive Wassermann reaction was obtained About six weeks later the patient was readmitted with a hard chancre, from which spirochætæ pallidæ were obtained Dr Volyansky promises that at the end of the war he will record all the other cases of the kind with which he has met, and his experiences will certainly be of interest It will be noted, with regard to the cases already considered, that the persons concerned were extremely likely to suffer from syphilis and therefore it was difficult to be sure that the positive Wassermann reactions were in no way connected with previous attacks

TENDER FEET AND VERRUCA PLANTARIS

DURING the continuance of the war, and perhaps now that active recruiting is taking place, it is striking that more is not heard of sound remedies for the cure or alleviation of the minor troubles of the feet Inasmuch as a very slight lesion or inflammatory reaction of the skin of the foot totally incapacitates a man for exercise, it is of the greatest importance that the foot should be kept as healthy as possible A large number of persons suffer from slight discomfort of the feet, which alters the gait as to make it at times quite awkward, but relief is not sought, either because it is not known where to apply for it or because the trouble may occur only intermittently—as, for instance, in damp weather The almost air tight boot may, of course play a part in acting as an incubator for micro organisms, and it is very certain that its inside is in most cases improperly aired It is therefore necessary to keep the skin of the foot, including the interdigital clefts, eminently clean, and when necessity requires it after the cleaning process it is useful to apply a disinfecting and soothing application, such as a 1 per cent carbolic acid and glycerine mixture or a two grain to the ounce salicylic acid and glycerine preparation Glycerine has been stated to modify the action of bacterial ferments and by its application alone in bromidrosis the manifest decomposition of sweat may be completely obviated[1] Many men have been disqualified by the examining officer for tender feet and corns, and doubtless many others who have gained admission to the army have, after repeated endeavours to overcome their inadequacy in marching, been invalided out from the same cause An important trouble which is sometimes classified as a corn on the sole of the foot and which is really a plantar wart or a nest of plantar warts—verruca plantaris—is usually extremely painful and incapacitating, and will often continue to recur after repeated operations for its removal by the knife and other means Many such cases, however, may be cured by the use of a combination of glycerine, salicylic and carbolic acid For an average sized patch the dressing is applied on a piece of lint about as big as a shilling, and oiled silk strapped over it The paste is made by taking an ounce of glycerine, adding enough salicylic acid to make a thick cream, and then mixing in one drachm of pure carbolic acid If the patient walk about with this on his foot for a day and re apply a fresh dressing the next morning it is often possible to peel away an area of thick sodden epidermis with the wart and its hard centre or core at one sitting, but it may be necessary first to apply a hot boric acid fomentation for a night to soften the area. Removal is best done by beginning at the periphery and peeling up gradually all round towards the central hard core After this the patient has a slightly tender foot which is usually quite comfortable within 24 hours The aspect of the area under treatment is sometimes disquieting to the patient, but as long as the application is kept strictly to the warty region no harm need be feared. It is, however, necessary not to permit the paste to reach the delicate ordinary skin, as it may cause an unpleasant form of blistering with subsequent formation of troublesome scar tissue Hence it is not desirable to let the patient carry out the treatment on his own behalf.

TYPHOID COEXISTING WITH DIPHTHERIA

THE coexistence in a patient of typhoid with diphtheria is seldom observed At a recent meeting of the Société Médicale des Hôpitaux of Paris M Joltrain stated that during last winter among the soldiers at the front there were epidemics of both diseases which gave rise to many cases of double infection with the typhoid bacillus or the paratyphoid (A or B) and the diphtheria bacillus In a barracks used as a temporary hospital for one army corps 4000 cases of pure typhoid and 796 cases of pure diphtheria were treated During a period of eight months 120 cases of typhoid or paratyphoid complicated with diphtheria were discovered, but this figure was below the reality owing to the great difficulty of the clinical diagnosis of diphtheria and the impossibility of bacteriological examination in all the cases Two distinct epidemics of diphtheria were observed among the typhoid patients at the time when a large number of cases of diphtheria were being treated The first occurred in December, January, and the early part of February, the second lasted from the beginning of May to July In investigating the etiology it was found that a certain number of patients admitted to hospital suffering from typhoid were also diphtheria carriers, as was shown by cultures made from their throats Later they developed diphtheria. In other cases patients suffering from typhoid contracted diphtheria in hospital from an *infirmier* who was a carrier or from a patient the subject of unsuspected diphtheria From the clinical standpoint three classes could be distinguished 1 Patients with the complete syndrome of typhoid cultures from whose throats showed the diphtheria bacillus but the typhoid did not appear to be modified 2 Patients suffering from typhoid showed a sore throat with membrane of which the diagnosis was easy The typhoid was always severe, though among eight cases there was only one death 3 In the largest class (59) the clinical picture was more complex, examination of the throat did not enable an exact diagnosis to be made Usually the patients were admitted from the sixth to the tenth day of an attack which differed little from ordinary typhoid Cultures from the throat revealed the diphtheria bacillus Detailed comparison with ordinary cases of typhoid showed some symptoms which were suggestive, especially those which could be attributed to the association of toxæmia of diphtheria with septicæmia of typhoid The temperature curve was more irregular than in typical typhoid, and in some cases the temperature remained stationary for 12 or more days In some cases at the beginning of convalescence, after the temperature had fallen by lysis, the general condition became worse, and without apparent cause the temperature rose again from normal to 101° or 102° F A most convincing phenomenon was the fall to normal of a very high temperature, which baths and other methods failed to reduce, after injection of antitoxin The general appearance of the patient was important There was great asthenia with facial pallor in 60 per cent of the cases Albuminuria was present in 84 per cent, while in typhoid in which cultures from the throat were negative it was present in only 20 per cent Vomiting—a condition very rare in typhoid in the absence of perforation or gastric ulceration —occurred in 18 cases The throat was carefully examined In 10 cases it was simply red In 12 cases there was œdema of the uvula with an opalescent pellicle on the palate and pillars of the fauces, difficult to distinguish amid the sordes encumbering the whole buccal cavity In 8 cases there was hoarseness, dysphonia, or aphonia, but the vocal cords showed nothing characteristic of either typhoid or diphtheria. They were simply dry, like the mouth and throat, and sometimes one or both cords were paretic. Thus cultures from the throat remained the criterion. But a positive result in cases of typhoid with a normal course indicates only that the patient is a diphtheria carrier It is best, however, to prevent possible complications and get rid of the bacilli by prophylactic injections of antitoxin On the other hand, when the bacteriological examination is negative diphtheria is not excluded with certainty

THE TREATMENT OF PHTHISIS BY SUN-BATHS

Dr W Holmboe gives a very encouraging account[1] of his experience with the treatment of pulmonary tuberculosis by heliotherapy at Mesnalien Sanatorium in Norway during the year 1915 Mesnalien lies in the open country between the Gudbrandsdal and the Østerdal, 1800 feet above sea level, in about the latitude of the Faroes[2] The snow lies on the ground there for perhaps eight months of the year, from October to May, and Dr Holmboe was at first inclined to believe that the climate would be altogether too cold for the sun bath treatment for the average temperature in winter is from − 5° to − 10° or − 15 C Experience has shown him that he was mistaken here, and that the patients can strip and take sun baths in open verandahs all the year round at Mesnalien, excepting in December and January, when the sun never rises sufficiently high above the horizon to keep the hardiest of them warm in an air temperature of – 3°C for more than half an hour If closed glass walled verandahs were available the sun bath treatment could be carried on with advantage all the year round even in this high latitude Dr Holmboe gives the sun baths in the hours usually devoted to rest, and without curtailing the exercise hours, he notes that sun baths have to be taken in solitude, and that this has the advantage of keeping the patients duly quiet during the rest hours He remarks that Norway naturally has less sunshine than Switzerland, the country especially famed for heliotherapy, but still has plenty to make the sun bath treatment worth while, he adds that on cloudy days therapy by radiant light should take the place of the sun baths, a suggestion already made by Rollier, of Leysin, and carried out in a majority of the Swiss sanatoriums, where a quartz lamp is considered part of the routine installation There was comparatively little sunshine at Mesnalien in 1915 during the first 319 days of the year there were only 150 on which sun baths could be taken, in July there were only seven! But the Norwegian sun is powerful even in winter, and a black bulb thermometer exposed in vacuo rose as high as 45°–55° C when placed in the sun in February or March, and to over 40° C in November Dr Holmboe observes that the great enemy of heliotherapy is the wind, he adds that the patients have to wear dark glasses to protect their eyes, and may be allowed to advance to the complete sun bath at about the ninth exposure, wearing broad brimmed hats to protect their necks The maximum daily duration of the baths has been 4½ or 5 hours, in two séances Only once has he seen any unpleasant effect from sunburn—an erythema, this was accompanied by fever and sore throat, and may not have been due to the sun at all His patients generally became much pigmented by the sun's rays According to Rollier the cutaneous pigmentation is to be regarded as a method of transforming ultra violet light into light of longer wavelength, which is more penetrating Reyn, on the other hand, argues that the pigment has the opposite effect of converting the light waves into ultra violet waves, and he regards it as harmful on the whole, whereas Rollier regards its occurrence as a good sign Dr Holmboe has had the same experience with cases of pulmonary tuberculosis as Rollier has had with surgical He finds that all his patients, without exception, were the better for the sun bath treatment, which gave them a feeling of well being and quiet, and facilitated the carrying out of the rest of the treatment The sun baths never raised the patients temperatures, but did sometimes produce a temporary quickening of the pulse, they improved the patients appetite Dr Holmboe finds a tendency to hæmoptysis the only contra indication to heliotherapy in phthisis, fever is not a reason for withholding sun baths, nor is the fact that a patient may have advanced pulmonary disease He has been surprised to find how well the treatment has suited all his patients, men and women, blondes and brunettes alike, whether it led to marked cutaneous pigmentation or no He concludes by praising heliotherapy in phthisis highly, it adds to the comfort and cheerfulness of these victims of a chronic and depressing malady, and is, indeed, the only treatment he has not found to be a disappointment

THE DEMAND FOR EXPLOSIVES AND THE FOOD AND DRUG SUPPLY

WAR in its demands comes sternly first Even certain foods are being sacrificed, it appears to supply the basis of the high explosive The only source of glycerine, for example, is the fats, and many fat yielding commodities are being pressed into service for the sake of the glycerine structure contained in them The final product is, of course, nitro glycerine The increased call for linseed lard, nuts, and cocoa illustrates the extraordinary hunger going on for the basic principles of explosives, derived from fatty food products Many, too, of our valuable drugs, and especially the synthetics, are similarly prevented from being economically prepared, since their elaboration is dependent on the use of raw materials, such as benzene, carbolic acid, toluene, all of which have been commandeered for munition service Recently a memorandum has been issued asking the public not to grumble at the quality of the gas supply and, further, to use as much gas as possible in order that the gas makers may get a bigger yield of benzene and toluene The withdrawal of these two substances from coal gas depreciates its illuminating power, though that matters little in these days of incandescent mantles, and when the use of the old fish tail burner has become practically extinct At one time we depended entirely upon the illuminating value, *per se*, of gas for lighting our houses and streets Now it does not matter if gas burns with a non luminous flame, it is so soon and effectively made radiant by putting in its path the rare earth resistance, the incandescing mantle It is wonderful to reflect what an extraordinary influence upon the world's affairs the producers of gas have shown since their inception of business as providers of an effective method of illumination They started to make gas for lighting purposes, and incidentally a group of by products appeared which proved to be the foundation of several most important industries In due time they began to supply fertilisers for the soil, antiseptics in surgery remedies in medicine, and dyes for the colour trades And now, in war their ploughshares have been turned into swords To take one example, we cannot now make aspirin or the salicylic derivatives in general economically because phenol, which is their starting point, is required for making picric acid, just as the glycerine in certain of our fatty foods is required for making nitro glycerine The same is true of many other synthetics, and also of the dyes There is no difficulty in producing them but there is a shortage of raw materials consequent upon the first call for their application being the making of munitions These considerations form one of the many serious outlooks of the war and we may well pray that this deflection of our raw materials into the service of war may soon cease

APPENDICITIS WITH THE CÆCUM ON THE LEFT SIDE

Dr C E Corlette has reported in the *Medica Journal of Australia* the rare condition of appendicitis with the cæcum and ascending colon on the left side He saw in consultation a man aged 42 for suspected appendicitis The temperature was normal and the pulse 96 and there were pain and tenderness referred to McBurney s point and also a little higher The pain had begun suddenly 24 hour previously, and had been severe all night. There had been no vomiting. Appendicitis was diagnosed, and the usual incision was made and the abdomen opened, but the appendix could not be found, nor could the cæcum or ascending colon. The right side of the abdomen was occupied entirely by small intestine. The incision was closed and a median opening made through which the abdomen was explored. The cæcum and ascending colon were found on the left side in contact with the descending colon, the transverse colon and omentum being absent. The appendix was long, swollen, and inflamed, and attached by a long meso appendix. The cæcum and ascending colon were furnished with a mesentery presenting a free border at the brim of the pelvis and attached along the middle line in front of the vertebral column. The rare anatomical abnormality present would be very disconcerting for an inexperienced operator, and might easily lead to abandonment of the operation with an untouched appendix. It is noteworthy that although the appendix was on the left side both the pain and tenderness were referred to the usual spot on the right side. This Dr Corlette does not attempt to explain. He has seen many cases of pelvic appendicitis in which the pain and tenderness were diffused in the hypogastric region with little or no localisation at McBurney's point. The October number of *Surgery, Gynecology, and Obstetrics* contains an article by Joseph H. Schrup on "Left Sided Appendicitis." He describes a case closely resembling the above. There was tenderness over McBurney's point, but at the operation the cæcum and ascending colon were absent from their usual place. The jejunum was coiled up in the right half of the abdomen. The cæcum was on the left side near the sigmoid. A radiogram taken later showed angulation at the splenic flexure and absence of the transverse colon, while the cæcum and ascending colon were in close apposition to the descending colon and sigmoid. Schrup has collected two other cases of similar anomaly recorded a long time ago, one by Cabot of Boston in the *Medical and Surgical Journal* of 1836, and the other by Cluene in the *Journal of Anatomy and Physiology* of 1867.

LOUPING ILL

A PAMPHLET published by Messrs Blackwood and Sons records the investigations of Dr J P McGowan, assistant superintendent of the Laboratory of the Royal College of Physicians of Edinburgh, into the disease in sheep known as "louping ill." There have been several inquiries into the nature of this malady but nevertheless its causes and pathology seem to have remained somewhat of a closed book. The research in this instance was carried out on behalf of the Edinburgh and East of Scotland College of Agriculture and the expenses incurred were met from the Development Fund through the Board of Agriculture for Scotland. In acknowledging that the subject of "louping ill" is a very intricate and difficult one the author controverts the idea that the disease is due to ticks and shows that it occurs on holdings and land where ticks have never existed especially in cases of low ground arable farms. He agrees however that where the tick is "louping ill" is always worse. "Louping ill" braxy, stomach staggers and grass sickness are considered to be essentially of the same nature but epidemiologically different. Braxy is the result of a sudden violent chill as a predisposing factor and "louping ill" is ascribed to a less violent one. The cause of the complaint is the bacillus bipolaris septicus ovium, which produces effusion into the pericardial sac and hæmorrhages in the heart muscle, mucosa of the fourth stomach and kidneys, and œdema of the lungs and subcutaneous tissues. Extreme variations of outside temperature, prevalent chiefly in spring and autumn, and improper or poor food supply render the subjects liable to attack. Lambs sucking an affected ewe may take the disease through her milk, and in them diarrhœa is a pronounced symptom. Shelter from bad weather, separation of ill thriving lambing ewes, and special feeding are recommended as preventive measures; affected pasture should be burnt, and the administration of a purgative to affected animals and their isolation are advocated as remedial measures. Injections of cultures of the bacillus into rabbits produced typical symptoms of the disease. The investigator does not consider the malady contagious, although recommending isolation, and he points out that cattle take the disease and are affected in the same manner as sheep. Navel ill, the œdema and pyæmia produced by tick bites, and wool ball in the stomach are cited as instances of pseudo louping ill. In the preparation of this report a circular of questions relating to "louping ill" was addressed to many who had knowledge of the disease and their answers to the questions put were very helpful to the cause of research.

SIR DYCE DUCKWORTH has been elected a Membre Correspondant Étranger of the Académie de Médecine of Paris.

WE regret to record the death, on Jan. 16th, of Dr Herbert Williams, medical officer of health of the Port of London.

RELEASE OF A MEDICAL MAN IN THE CAMEROONS.—Official notification has been received of the release, on Jan. 8th, of Dr James Lindsay, of the West African Medical Staff by a British force from his captivity in the Cameroons. Dr Lindsay was captured by the Germans shortly after the outbreak of war and interned near Jaunde.

A DOMESTIC ECONOMY EXHIBITION.—On Jan 17th at the Institute of Hygiene, Devonshire-street, W. Princess Louise Duchess of Argyll, opened an exhibition, the object of which is mainly to indicate some of the ways in which waste in the household can be prevented. Her Royal Highness pointed out that although much of the waste in our kitchens is due to carelessness some must be credited to an ignorance which may be removed by instruction. Sir William Bennett the President read an address of welcome. The exhibition will remain open from 12 to 6 until Saturday. To-day (Friday) at 3.30, Dr J S Owens will lecture on Waste in Fuel.

DUNDEE'S LOW BIRTH-RATE AND HIGH DEATH-RATE.—For the year 1915 the birth rate in Dundee was just over 22 per 1000 inhabitants compared with 28 per 1000 in 1905 24.5 in 1913 and 25 in 1914. Previously the falling birth rate was offset by a falling death rate. In 1915 this was not so the surplus of births over deaths being only 165; in the worst of the previous years it was never below 1500. Among children under 1 year of age the proportion of deaths was 210 for every 1000 born. A contributory cause of this high mortality was the occurrence of two severe epidemics of whooping cough, while measles prevailed in the city in the early part of the year. Whooping cough also accounted for 305 deaths causing the heaviest death rate from whooping-cough known in Dundee. The death rate from measles although high has been exceeded on one or two occasions.

STRETCHERS FOR THE WOUNDED IN THE TRENCHES

BY G H COLT, F R C S ENG,
CAPTAIN R.A.M C (T F) ASSISTANT SURGEON, ROYAL INFIRMARY ABERDEEN

ON August 15th, 1915, I received a letter from Captain D'Arcy Power, R A M C (S R), at the front, in which he says —

> We are in most urgent need of a stretcher for use in the trenches Although we have all for months past been trying to devise something all our efforts have failed so far The communication trenches are very long in certain parts of the line They are 27 inches wide at the level of the hip and 29 inches wide at the level of the neck. They have no traverses but they bend about in rather sharp curves and are 6 feet deep The fire trenches are 19 inches wide at the level of the hip and 25 inches wide at the level of the neck, and are 9 feet deep They are formed with traverses of 6 feet at intervals of 20 feet and the chief difficulty is in getting round these—i e in turning the corners The diagonal width across the corner of such a fire trench is 29 inches at the level of the hip and 32 inches at the level of the neck. The regulation stretcher fails utterly, but in a communication trench where there are no traverses but only bends the bearers may hold the stretchers at arms' length over their heads The fire trenches are too deep for this even if it were safe My dressing station was situated 800 yards behind the front-line fire trench, and with our present lack of suitable stretchers it took anything from 1½ to 2½ hours to bring a wounded man 800 yards back this distance. Then if it was an urgent case and it was daylight he had to be man handled down another 800 yards of trench to a village where a motor ambulance was stationed If the case could wait till dark the ambulance was able to run up to the dressing station and thus save this second 800 yards of carrying but even in the dark the car was able to get up no further as the road was all shell holes

Now, after a year of war, and especially after the publication of Captain G K Aubrey's article[1] drawing attention to the need of stretchers for the wounded in the trenches, it is unfortunate that more experimental work on the subject has not been published Such work could only be carried out with difficulty if done on active service, whereas many surgeons at home might be able to design a pattern of stretcher that would prove efficient Early and quick transport is probably of equal importance as if not of greater importance than, the application of a field dressing There is nothing difficult about the manufacture of Aubrey's stretcher It consists essentially of two poles each 4 feet long Each is provided with a hinged leg, which when let down enables the stretcher to be balanced while the bearers take a rest The width of the stretcher when fully expanded is 20½ inches There are no traverses The patient sits with his back and head against the chest of the back bearer and his legs hang down

From the measurements of the fire trenches given in the letter the maximum length diagonally across the convex angle of the corner measured at right angles to the line joining the convex and concave angles is only 4 feet and this is reduced to 3 feet at a distance of 9 inches from the convex corner Aubrey's stretcher could not possibly pass round a corner in so small a trench in the ordinary way Since there are no transverse props in this pattern of stretcher, by compressing it laterally and tilting it sideways or upwards it might be made to pass at the risk of tipping the patient out or of causing him pain He may be secured, as Aubrey suggests by a band across the chest This stretcher was made on the spot, it proved of much service and several were soon in use in the brigade, but Aubrey had no doubt that it could be improved, and hoped that suggestions to enhance its value would be made by others In a letter which followed his article, signed "W J M E,"[2] the suggestion was made to adapt a wheel barrow for the purpose of negotiating the sharp turns of the spurs thrown out to protect the trench from enfilading fire "Shallow troughs could be fixed on either side of the wheel, and in these the patient's legs could be laid Where the bearer company was insufficient to deal with large numbers of the wounded, it would be possible to manage a case with only one bearer" "W J M E" also suggested that when mud and water prevented this method of transport a chair carried on the tilt with lashed poles and side ropes to prevent an insensible patient from falling out could be used

The measurements of the trenches given above are less than those shown in the sketches in "Field Service Pocket Book, 1913," and no doubt exigencies of service, greater safety, and the nature of the soil demand different measurements in different localities To be obliged to place men in a trench so narrow that even two unwounded persons cou only pass with difficulty and to be unable to provi a quick and efficient means of moving them alon it when wounded is unsatisfactory New trench also may in some respects be more difficult traverse than those in which the corners have bee worn away It should be noted that even a sma rounding off of the convex angle at any corner mak a relatively large difference in the ease with which stretcher can negotiate it and adds very little to th risk from enfilade fire Baying out the concav angle has much less effect as regards ease movement

Methods Tried

The officers and men had tried —

1 A single pole stretcher with the canvas slun below it by cords like an Indian "doolie" o "dandy" The pole had a joint in the middle, an failure had resulted as no satisfactory joint coul be evolved This was one of the best arrangement tried The failure of the Indian dandy to negotiat the corners and slopes in mountain warfare is wel known

2 Rogers's stretcher The poles are 3 feet 6 inche long Bands for the shoulders are attached to th upper end of the upright portion of the canva which is thus held up by the front bearer, agains whose back the patient leans As in Aubrey stretcher the patient sits with his legs hangin down The length of the seat is 23 inches and th width 18 inches As a matter of experience it wa found that most of the weight came on the front bearer The stretcher could not be lowered to the ground with a badly wounded man in it, and so the bearers could get no real rest An unconscious patient was apt to roll off, as the hands of the bearers were fully occupied and there was no room for a third man to hold him on

3 A chair tied on to two poles and carried with the seat tilted slightly This arrangement answered well in some cases and was readily improvised A disadvantage of it that was not mentioned is that when used for a patient with a fractured femur the seat is too short to act as a splint and its front edge may act injuriously so as to cause further displacement of the fragments

---

[1] THE LANCET Dec 26th 1914 p 1433

[2] THE LANCET Jan 2nd 1915 p 45.

4 A blanket or ground sheet carried by the corners This is in common use, but is often difficult and tiring to manage For unconscious patients liable to suffocate, for "gassed" patients, and for cases of fracture of the lower limbs this method is most unsuitable The same objections apply to any stretcher of the hammock type in which no prop is provided to keep the bearers the same distance apart

It is apparent from the foregoing that the problem is one of some difficulty Such questions as lightness, the possibility of setting the stretcher down for the bearers to rest, loading and lifting the stretcher, passing men and boxes in the narrow spaces, and above all causing as little pain and injury to the patient as possible, have to be considered At present the bearers soon get knocked up The advantage of Aubrey's stretcher over Rogers's is that it has two folding legs which can be let down, and the stretcher is then balanced while the bearers rest Soft ground must result in difficulty in this respect Shoulder bands also may be used for the suspension I am told that any rigid stretcher which has no traverse is tiring for the bearers to manage In both these types the patient is apt to roll off, and it is a question whether the sitting up position is a good one for any unconscious patient In both cases the patient's legs hang down There is no great disadvantage in that provided they do not knock against uneven ground and are not kicked by the adjacent bearer If there is a fracture of the leg bones extension will be made by the weight of the limb and the boot A bayonet or other simple short splint could be lashed to the leg below the knee The advantage of the position is that the carrying length of the patient is comparatively small In the trials carried out by us it was found that it was a disadvantage to provide an extension piece to the canvas for supporting the legs and feet because of the varying length of leg in different patients Such supports are uncomfortable even in the absence of injury may lead to further injury if a fracture is present and if made adjustable are apt to be too complicated A simple stirrup is one of the best of such supports and can be readily improvised by tying on a sling of bandage in the required place From the illustrations[3] given of a further development of this type of stretcher it would appear that the vertical supporting poles could readily be used for splinting the outer sides of the patient's legs The ends of such props and the ends of any upward projecting pole or back rest catch in the sides of a trench when the stretcher is tilted sideways

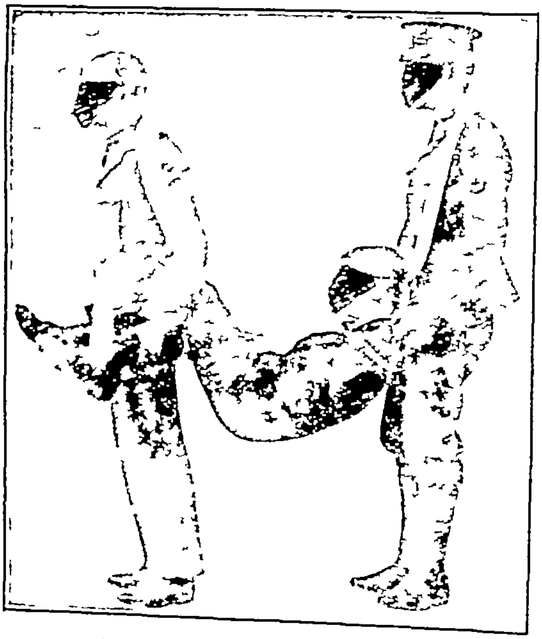
The "Fowler Position"

Now it seems to me that the Fowler position, or a near approach to it, would be a better one than the sitting up position In the case of an unconscious patient there is not the same degree of risk of his falling out and he is more readily controlled if he is restless For thoracic and abdominal cases, more especially cases of commencing peritonitis, the position is one of the best if not the best that could be chosen For a case of fractured femur it is not by any means bad because the support lies evenly from the buttocks to the knees, but if the fracture were near the knee joint it is at present a matter of trial to see how the position answers For a case of injury to the leg especially a fracture, as already mentioned, the only disadvantage is the risk of the injured limb being knocked by obstacles or by the adjacent bearer For cases of severe collapse or shock the position is not the best theoretically, but the speed with which the vascular system adjusts itself to the maintenance of blood pressure, even in severe cases, is often remarkable, and the cause of the collapse may be peritonitis The Fowler position, especially if maintained by a rigid system, can be quickly reversed so that the head is low and the pelvis high Some years ago Colonel H M W Gray had constructed for him a rigid tray with canvas floor, after an American pattern, for the purpose of moving patients in the Fowler position from an operation table back to bed in a nursing home where there were one or two awkward corners on the stairs The patient could by this means be tipped up nearly vertically, and in this way the contrivance readily negotiated the corners The great advantage of the Fowler position for present purposes is that the carrying length of the patient is seldom greater than 4 feet, and is usually less than this

The Flexible Method

Attempts to utilise the position may be made in three ways—viz, the flexible, the semi rigid, and the rigid In the first a strip of canvas 5 feet long is taken, and at one end it is fastened to a transverse knee piece which is suitably curved so as to partially splint the back of each knee and maintain a distance of some 4 inches or more between them.

FIG 1



The "Fowler position": flexible method

At the other end a rounded head frame is attached and continued down to the shoulders, where a cross piece, suitably curved so as to be comfortable, is fixed about 12 inches from the top of the head piece The shoulder piece and head frame are in one piece, so that the traction applied to the top of the shoulder piece, together with the weight of the patient acting along its lower border, tend to keep the head piece upright The length of the finished sling is 4 feet 6 inches, and the width of the knee piece and shoulder piece and the canvas stretched between them is 16 inches This is ample for almost any patient, and less will do, especially at the knee The edges of the canvas are turned over two side ropes which join up the corresponding ends of the knee and shoulder pieces These ropes are slightly shorter than the length of the canvas so as to give it a transverse bay like the sag of a much used deck chair or a hammock The side ropes can be omitted with certain kinds of canvas To the ends of the shoulder and knee pieces webbing shoulder bands are attached by hasps and rings Fig 1 gives an idea of the arrangement, and it is apparent that the method is really an improved form of the blanket stretcher It is certainly more comfortable both for the patient and the bearers than a simple "fore and aft" carry Suitable bands can be added to restrain the patient, the chief situations for these being just below the axillæ and just above the knees The height of the lowest part of the patient from the ground is about 1 foot 10 inches No provision has been made in this arrangement for keeping the bearers the same distance apart during transit The lack of this and the sideways spread of the feet with insufficient room for his legs are the chief objections to this method of carrying a patient The weight is 5 lb

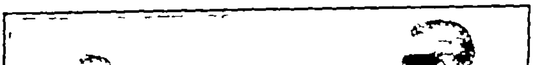
---

[3] THE LANCET, Oct 23rd 1915 p 822

The Semi rigid Method

In the second or semi rigid method the part of the stretcher in which the patient reclines is of the type described above It may conveniently be suspended in two ways The first is by means of two side poles each 4 feet long, as illustrated in Fig 2 The poles are attached to the shoulder and knee pieces by hasps and swivel rings which can easily be released Webbing slings may be added for the shoulders of the bearers A hinged prop may be provided for each pole as in Aubrey's stretcher, so that the apparatus may be balanced on hard ground, and allow the bearers to rest It seems to me that for simplicity it is better to omit the supporting props and to rely on other relief in this respect. The objection to these props in any short poled stretcher is that when dependent they catch in the wall of the trench and the feet of the adjacent bearer directly the stretcher is tilted sideways If the ground is soft they are apt to sink into it. For small shields could be added near the outer side of the ends of the handles of any short poled stretcher so as to prevent the knuckles of the bearers from being scraped by the walls of the trench This would appear to be a much needed improvement From the figure it will be seen that the only rigid part of the sling between the poles is the head frame, and the poles may be approximated to this extent when turning a corner The outside width of the two poles is then only 11 inches. This allows the stretcher to negotiate a right angled corner in a trench 28 inches wide, but the bearers require practice for this, the patient's feet are apt to catch in the sides of the trench and more weight is thrown on the back than on the front bearer This stretcher might be regarded as a modified form of Aubrey's, with the substitution of the Fowler for the sitting up position, with a reduction in width of 4½ inches, and with the additional traverses It folds up for packing The weight of the apparatus complete is 11 lb In any stretcher of this type it is difficult to reduce the effective length of the poles below 4 feet This leaves barely sufficient room for the patient's legs, even if the front bearer were to manage to walk quite evenly The lowest part of the patient is only 10 inches off the ground

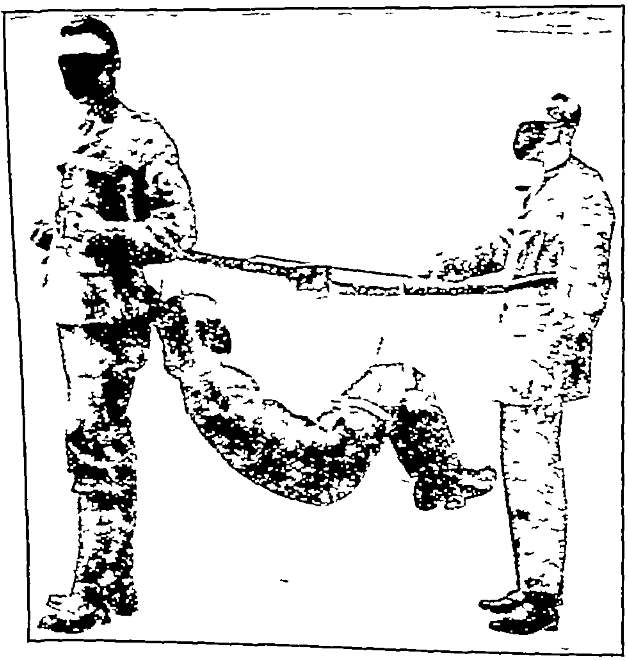
FIG 2



The "Fowler position" semi rigid method

In the second form of stretcher of the semi rigid type the suspension is from a jointed pole, as shown in Fig 3 The pole proper is of larch, the yokes of sarch, a wood of the willow type, tough and light This avoids any risk of the yoke splitting across the ends, but if the yokes were made of bent wood as would probably be the case in manufacture, there would be no necessity to use sarch The suspension is by ropes with hasp and eye attachments The pole is divided into two parts which engage at the central joint This is conveniently effected by a simple nut and bolt allowing movement in a horizontal plane Now it is found that directly every slight displacement occurs at the joint, forces come into play which cause a couple to act the moment of which about the joint tends to increase the displacement, the condition being one of unstable equilibrium Unless some kind of stop were provided disaster would follow, the pole collapsing completely In the course of the experiments one of the journeymen carpenters solved this part of the problem after a few trials It is by far the most important part of the matter He provided a lever and handle situated above the pole This addition results in complete control of the joint, and is in itself a very beautiful piece of mechanics The front end of the lever is fixed to the front part of the pole, the fulcrum is at the joint, and the handle moves free The back bearer by moving the handle determines the exact degree of bend at the joint and restores the same as required By suitably pressing on the handle in an upward direction he is able to prevent any tendency that he feels may exist for the joint to collapse When the pole is straight the handle of the lever can be locked to the back part by a hasp so that the pole is held rigid and the hands of the bearer are freed For certain special cases, such as the use of the stretcher on spiral stairs cases, a side extension bar may be affixed so that ngage the handle by stops and so enable the parts of the pole to be locked at any required e This bar is not illustrated To utilise the retical advantages of the lever fully the ard end should be attached at a point distant i the joint equal to one sixth part of the length he pole and the handle should be one third of distance from the joint, but in actual practice i these measurements may be departed from iout much loss of efficiency, and as regards the dle end of the lever with some degree of gain iuse a shorter handle is less likely to scrape inst the side of the trench It is to be noted in turning a corner the handle projects towards concave angle of the trench while the stretcher otiates the convex angle One great advantage this type of stretcher is that other men in the ach are able with care to step around and pass it an early pattern of this type, since discarded, the es were borne on the shoulders of the bearers e great disadvan es of this system re the difficulty of sing the yokes on the shoulders of e bearers and the ex ssive strain thrown the back bearer e had to resist the ndency to deforma on of the pole, and this position this ight be very hard ork indeed The front earer was subjected pressure on the two ioulders alternately, ccording to the direc on of turning The ict, however, remains s a result of trials hat this type of tretcher with the ole 6 ft 3 in long ver all, and the yokes 2' in wide outside neasure could just be nade to pass round he corners in a trench 8 in wide and one n which the convex corners are sharply ut As already mentioned, if these corners are rounded off slightly the ease of passing them is largely increased

FIG 3

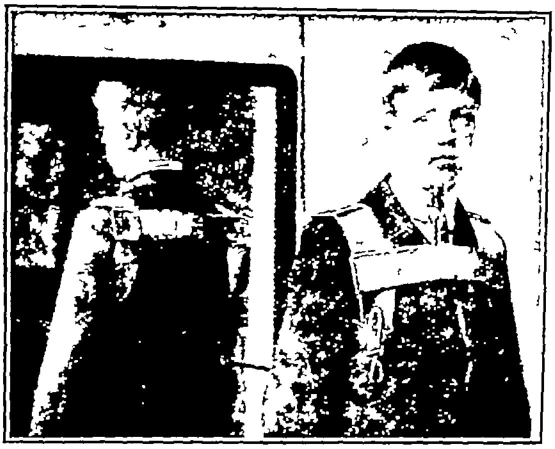


The "Fowler position" suspension from a jointed pole

In order to try to overcome the great strain on the bearers and the other disadvantages of the earlier pattern the suspension shown in Fig 3 was designed In this the yokes of the pole are suspended from the shoulders of the bearers so as to be level with the lower part of their chests, which they fit fairly closely They may also be held in the hands At times notably on a straight stretch, the bearers trust the weight to the shoulder slings entirely The lever in this case is worked by pulling from above it instead of by pushing it from below and the back bearer may have two hands free for this purpose The distance of the patient from the ground being less than when the yokes are carried on the shoulders the consequences for all three are not likely to be so serious should any accident happen but the patient is more likely to become soiled by mud The weight is more evenly distributed between the bearers, but the front bearer is purposely given more than the back one This method of suspension is a great improvement on the last and the strain on the bearers is considerably less The apparatus, in fact, becomes a manageable thing The over all length is 5 feet and the outside width of the front or larger of the two body girdles 15 inches The total weight is 23 lb There is no doubt that this could be reduced to 18 lb and possibly less with safety to the patient The lowest part of the patient is about 16 inches off the ground The stretcher can be loaded and will pass round right angled corners in a trench 18 inches wide During his transit in such a narrow trench the patient scrapes the corner If conscious and able to use his arms he can assist by pushing himself away from it In a wider trench this would not be necessary The increased ease of movement is marked and there is just room for the patient's legs Throwing more weight on the front than on the back bearer compensates the latter for his exertion in working the lever and enables him to keep a good look out A disadvantage of carrying the patient backwards is that the back bearer has no means of controlling him if he is unconscious The assistance of a third man is required in hasping up the bar to the shoulder straps of the bearers and in releasing them, but otherwise two bearers can manage alone In a winding trench 20 inches wide having no sharp corners but merely sharp bends there is very little difficulty in walking quickly with a patient slung as here described In a cornered trench 22 inches wide there is not much difficulty, and in one 24 inches wide the bearers can walk quickly with ease No short poled stretcher yet designed can be made to negotiate a corner with comfort to the patient and ease to the bearers in a trench 26 inches wide

The question arises as to how the patient is to be placed in a stretcher of this type No doubt much will depend on circumstances Probably the patient will be carried to the nearest spot where the trench widens out, and then lifted into the sling In other cases it may be more convenient, especially if the bottom of the trench is dry and there is room to move a little, to unhasp and spread the canvas on the floor of the trench and lift the patient lengthwise, or lift or roll him sideways on to it In doing this the important point to remember is to place the knee piece directly under the knees, the rest is self adjusting as regards length The head end of the canvas is placed in the direction of transit Then, if necessary, the restraining bands will be adjusted, the bearers will take up position and stoop down, holding the yokes while a third man fits the hasps to the eyelets of the canvas The back bearer will lock the lever

FIG 4



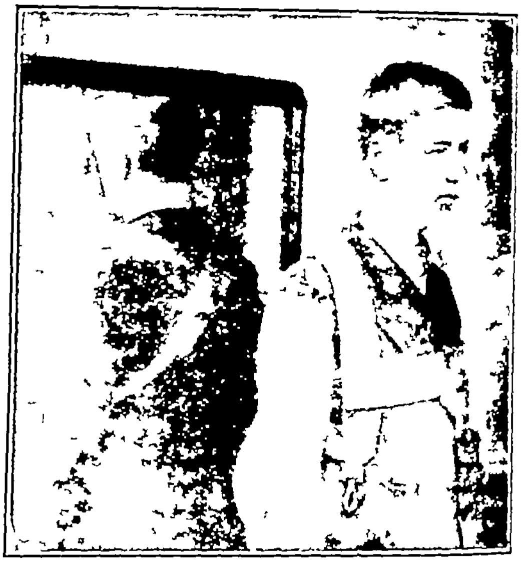
True shoulder suspension.

The stretcher will then be lifted and hasped on to the shoulder slings In certain cases the patient's head will be turned on one side and bandaged or strapped to the headpiece In other cases, one or both of his feet will be placed on the chest or shoulders of the back bearer and a long splint applied from the hip The back bearer will unlock the lever and the party move off

The bearers could obtain rest either by working in relay stages or by providing at intervals poles with a fork or crutch at the top in which the bearing pole could be balanced and the canvas kept off the ground If there should happen to be a convenient dug out or other ledge, the sling can be swung sideways and set down on it The soldiers would always offer a hand for temporary relief With this type of suspension the bearers cannot set down a heavy patient unaided on to the ground on which they are walking, and even with a light patient there is a strain on the knees when attempting to do this On the return journey other bearers could easily carry a 10 stone weight of food and ammunition for distribution along the fire trenches

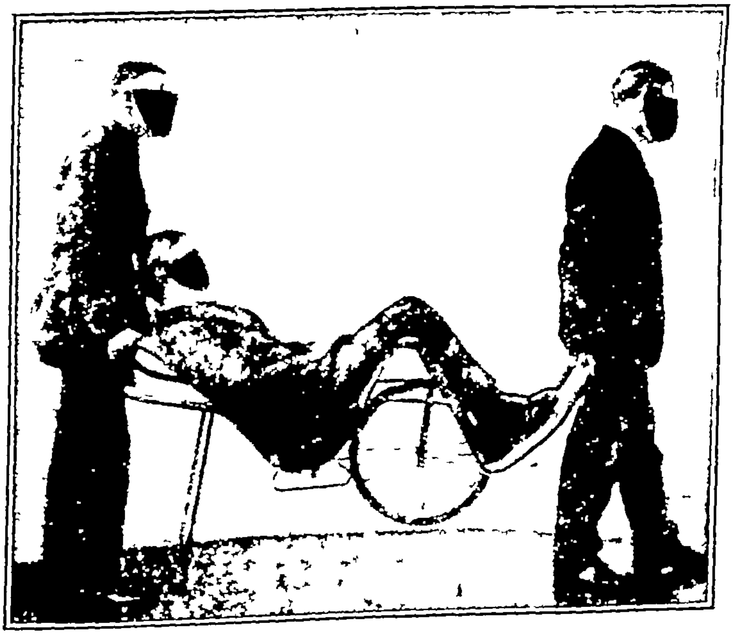
The regulation method of so called shoulder suspension is by a band of webbing as shown in Figs 1 and 2 In actual practice, especially durin lifting and setting down, this becomes raised up on to the bearer's neck and the strain is much greater than it should be, partly, no doubt, owing to actual constriction and partly to the muscular effort compressing the veins of the neck and leading to retention of waste products in the muscles The true shoulder suspension illustrated in Fig 4 is a great improvement, bringing as it does the weight direct on the shoulders and removing it entirely from the neck In the short suspension required for the jointed pole stretcher a difficulty is to obtain arm hole room, and in the case of the actual collar illustrated the bearer has some little difficulty in adjusting the collar himself These objections can be got over by omitting the horizontal back band, lengthening the webbing, crossing the two ends over the back and carrying them round to join the front pieces under the opposite axillæ as shown in Fig 5 This pattern also is more easily constructed In a longer type of webbing suspension these difficulties do not arise and it would be a humane thing if some such

FIG 5



Improved form of the same

FIG 6



The "Fowler position," the right method.

houlder collar as described were substituted for he regulation band now in use The bearers vould not get knocked up nearly so much, n fact, the total gain considered over the whole front after an action would be consider ible Without this improvement the jointed pole stretcher would not have come to fruition, whereas it the present time it would appear to be the only stretcher that will efficiently accomplish its purpose in fire trenches 18 inches to 26 inches wide

In the stretchers described the sling in which the patient is placed is distinctly comfortable to recline in, and the feeling is one of even support for the whole of the body with the exception of the lower part of the legs

The Rigid Method

In the third or rigid method of using the Fowler position the suggestion already referred to, to employ a modified wheelbarrow, has been carried out Fig 6 shows one of the experimental pieces of apparatus, which in this instance has been made of cycle tubing and sheet metal It is 4 ft 6 in long, 15 in wide, and weighs without the under carriage 25 lb When carried it will just negotiate a right angled corner in a trench 29 inches wide, and when wheeled it will pass in one 26 inches wide By reason of its shape the tray portion is a complete natural splint for the head, neck, body, and lower limbs It may be carried tilted up, horizontally, or tilted down and could be swung nearly vertically over the side of a ship or down the shaft of a mine with scarcely any disturbance of a strapped in patient The under carriage for the wheel or wheels can be made detachable, and if conditions for wheeling were suitable it could be left on the return journey at the end of the communication trench ready to be utilised for running the next case along, but if preferred it could be hooked on at the back In order to lessen the load on the back bearer when wheeling the stretcher the axle should be set far back, nearly under the patient s centre of gravity, but unless the height of the axle off the ground is increased this setting back decreases the efficiency in turning a corner Setting the axle well forwards increases this efficiency by reducing the turning length but it would appear to be unlikely that this length between perpendiculars can be reduced below 3 ft 2 in, in which case such a stretcher could just be made to scrape round a corner in a trench 22 inches wide In some trenches illustrated in the weekly papers there is a false bottom of planks under which the water lies In these trenches the use of this pattern of stretcher might be found to be a quick and easy means of moving a patient It is also probable that when perfected it would answer for general transport work, but not necessarily for lying down cases when deposited in casualty clearing stations or ambulance vans The manufactured article would be a simple tray of metal stamped in one piece and rimmed up with light tubing After removing the under carriage such stretchers could be packed up like saucers one on the top of the other, and so be made easily portable for use in quantity In civil work, and perhaps in some forms of military work four wheels would be used with this form of stretcher Owing to the difficulties of obtaining materials and labour the further experiments with this type of stretcher are likely to take a considerable time I therefore thought it best to publish this article now instead of waiting for their completion, so that others may be able to assist

The photographs from which the illustrations have been made were taken by Messrs G and W Morgan, of Aberdeen, who have spared neither pains nor experience to illustrate the details In carrying out the designs and trials, the help and suggestion of numerous friends have been invaluable, and I take this opportunity of offering them my grateful thanks There is little doubt that others will already have thought of and tried some of the general designs, especially the more simple ones, indicated in this article, and in this respect I particularly do not wish to claim priority The matter seemed to me to be an important one, and as such to be deserving of attention I hope that the general outline given of this particular part of the subject—viz, the utilisation of the Fowler position for carrying patients in stretcher work—may help towards a practical solution of the problem

---

CANADA

(FROM OUR OWN CORRESPONDENT)

Vital Statistics in Canada

ONTARIO has probably the best system of registration of any of the provinces of Canada, as regards births, marriages, and deaths It has been registering for over 45 years, but it is claimed that one in every five births escapes registration Canada is said to be very far behind other British Overseas Dominions in regard to the compilation of vital statistics, and if the above statement is correct—and there seems to be no doubt of it as it comes from a responsible source—then the other provinces of Canada which are not up to the standard of Ontario in health matters must have a very nominal vital statistics department

An Important Legal Decision

An action was recently brought against a Canadian general practitioner The plaintiff was a woman who consulted her physician about a lump in her breast The physician, at the time of the examination, detected a lump in the other breast as well A surgeon was consulted and the first breast was removed At the operation, and while the patient was still under the anæsthetic, the physician told the surgeon there was a lump in the other breast and that he had secured the patient's consent to the removal of both lumps The double operation was done Some time later trouble arose in the arm corresponding to the second operation An action was brought against the surgeon for assault, the patient claiming that he had not had her consent to the double operation The case came to trial, and there was a conflict of evidence between the patient and her physician, the latter claiming that the patient had given to him her consent for the removal of the second breast Having heard a considerable amount of evidence in the case, the justice held that a surgeon is justified in performing an operation additional to the original one where the case demands that more be done than was at first considered proper A surgeon might, in fact, be open to blame if he failed to perform a second operation where he found such necessary for the cure of the patient

The Universities, the Medical Council, and the Ontario Medical Commission

President Falconer, of the University of Toronto, appeared before the Ontario Medical Commission, which is inquiring into the regulation of medical practice in that province, and stated that dual control of examinations by the universities and the Medical Council was humiliating He contended that once a student of medicine got his degree he should be entitled to practise At present the degree of the University of Toronto was at a disadvantage throughout the empire The Ontario Medical Council did not recognise it, consequently it could not be recognised by the General Medical Council of Great Britain The Ontario Medical Council now has the legal right to set the course of the University curriculum A few years ago it gave up holding primary examinations, but retained the final examinations Counsel for the Medical Council of Ontario held that the final examination by the Council was necessary in order to show that after his five years' tuition at the University the student was really efficient to practise The Council, whilst admitting that the medical student has undergone satisfactory academic training, has no means of confirming this other than by examination Thus the universities and the Council are pulling against each other before the Commission The universities wish for full control over examinations, thus relegating to the Medical Council a purely disciplinary function over the profession in the province

Free Serums for Ontario

The Ontario Board of Health has undertaken to supply free practically all the serums of different kinds used in that province The annual saving to the people will run into tens of thousands of dollars Of diphtheria antitoxin alone it is expected that 150,000 to 200,000 doses will be needed per annum and about 500,000 doses of antityphoid vaccine The latter has already been supplied gratis to the troops of the whole Dominion of Canada, as well as to those of Newfoundland One circumstance largely responsible for the adoption of this principle by the Board of Health was the observation of the results of the gratuitous distribution of diphtheria antitoxin in Toronto The general death rate in Toronto from diphtheria is 16 per cent, while in the Toronto Isolation Hospital, where the severest cases are generally found, the death rate was only 6 per cent In the hospital the serum was supplied free and in large doses Last year the Board of Health was able to supply diphtheritic serum at a quarter of its original price and this has paved the way for the general manufacture of serums by the province

Toronto Jan 4th

CENTENARIANS —Mrs Mary Paige, of Albany-road Rochester, has celebrated the 100th anniversary of her birthday and has received a congratulatory letter from the King She was born at Launceston Cornwall —The death is announced of Mrs Rebecca Law an inmate of Saffron Walden Union, at the age of 102 She was in possession of all her faculties

DONATIONS AND BEQUESTS —The Aberdeen Royal Infirmary has benefited to the amount of £700 under the will of the late Mr Alexander Fitchet of Carnoustie The sum is to be paid free of duty —Cardiff Hospital has recently benefited by an anonymous gift of 10,000 guineas towards the cost of new extensions and by a donation of 1000 guineas to endow a bed by Messrs Watts Watts and Co coalowners The hospital has received four gifts of a like amount from various donors during last December

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE undermentioned have been entered as Sur temporary service in His Majesty's Fleet —Dated Jan Robert Aitken and Samuel Parker Mort.

ARMY MEDICAL SERVICE

Lieutenant-Colonel Joseph F M Kelly to be temp Colonel whilst employed as Assistant Director of M Services of a Division (dated Dec 7th)

Major William M B Sparkes to be temporary Lieu Colonel whilst Acting Assistant Director of Medical Ser of a Division (dated Nov 20th)

ROYAL ARMY MEDICAL CORPS

Temporary Major Charles S Myers to be temp Lieutenant-Colonel (dated Jan 18th)

Temporary Captain Robert J D Irvine to be temp Major (dated Jan 14th)

Temporary Lieutenant William J G Garton to be tem porary Captain (dated Dec 7th)

Temporary Lieutenant Norman K Wilson to be temp Captain (dated Jan 15th)

Temporary Honorary Lieutenant Angelo M Cab relinquishes his commission on ceasing to serve with New Zealand War Contingent Hospital (dated Jan 3rd

The undermentioned to be temporary Lieutenants —

Dated Dec 27th Evan Parry Evans

Dated Dec 28th Joseph Chamney Atkinson Rid Helton Godwin Baynes, Henry Currie Watson, Fr George Thomson, Henry Stewart, John Patrick O Co James Dewar Robertson, Henry Catling and S Langstaff Haslett

Dated Dec 29th Hubert Sewell Sims and Reginald Moore

Temporary Lieutenant-Colonel Leonard S Dal relinquishes his commission (dated Dec 27th)

Temporary Captain Charles N Binney relinquishes commission (dated Dec 10th)

The undermentioned temporary Lieutenants relin their commissions —

Dated Oct 24th John W O Farrell

Dated Nov 1st James W Richardson

Dated Nov 2nd Francis K Kerr

Dated Nov 10th Denis G Halsted

Dated Nov 17th Maurice C Turiansky

Dated Dec 1st Charles W Hamilton, Joseph L Bar Ricardo Cope, Arthur N Leeming, Joseph G Macq Andrew T Ross John F Gibbons William J I Ma Mackenzie Douglas and John C L Day

Dated Dec 4th Reginald W Clark, John G McDou William G Helsby and James Potter

Dated Dec 7th Charles C Holman, Lynne Bor John C McConaghey, Roderick A Campbell, and R Fleming

Dated Dec 10th Wilfred H W Attlee and Allan F Wilson

Dated Dec 14th John Anderson, Richard F Worthin ton, and Walter J Harper

Dated Dec 15th William F Dunlop, Horace F H Tracy, George B Horrocks and George J B Candler Ho

Dated Dec 16th William Readman, Charles T Bishop, Ernest G Wheat, John Duffin, Edward H A Pask an Douglas Elder

Dated Dec 17th Bertram M Bone

Dated Dec 18th William McH Binning and George F Phillips

Dated Dec 28th Michael Sullivan, John H Dougl Sylvester D Fairweather and Herbert D Robertson

Dated Dec 30th Richard F Sedgwick and Willia Taylor

Dated Jan 16th Randal MacCarthy

Overseas Contingents

The British West Indies Regiment

Albert James Clarke to be Surgeon Captain (dat Sept 18th)

The undermentioned to be Surgeon Lieutenants —

Dated Sept 19th William Steele Mitchell

Dated Nov 8th Aldington George Curphey

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN the 96 English and Welsh towns with populations exceeding 50 000 persons at the last Census, 7665 births and 4850 deaths were registered during the week ended Saturday Jan 15th The annual rate of mortality in these towns which had been 14 9, 16 6, and 14 3 per 1000 in the three preceding weeks, fell in the week under notice to 13 9 per 1000 of their aggregate population, estimated at 18,136 180 persons at the middle of the year 1914 During the 13 weeks of last quarter the mean annual death rate in these towns averaged 15·5, against a corresponding rate of 16 2 per 1000 in London The death rate last week ranged from 6 8 in Southend on-Sea, 8 2 in Bath, 8 6 in Ilford 8 7 in Wolverhampton and 8 9 in Swindon, to 19·0 in Middlesbrough, 19 8 in Barrow in Furness, 19·9 in Walsall, 20 1 in Dudley, 20·3 in Barnsley, and 21 5 in Stockport

The 4850 deaths from all causes were 140 fewer than the number in the previous week and included 329 which were referred to the principal epidemic diseases, against 355 and 312 in the two preceding weeks Of these 329 deaths, 84 resulted from diphtheria, 78 from whooping-cough, 75 from measles 60 from infantile diarrhœal diseases, 23 from scarlet fever and 9 from enteric fever, but not one from small pox. The annual death rate from these diseases was equal to 1·0, or 0 1 per 1000 higher than in the previous week The deaths attributed to diphtheria, which had been 61, 79, and 61 in the three preceding weeks, rose to 84 and included 19 in London 4 in Liverpool and 3 each in Hornsey Portsmouth, Birmingham Sheffield, and South Shields The deaths referred to whooping-cough, which had been 69, 60, and 57 in the three preceding weeks rose to 78 of which 15 were registered in London, 8 in Liverpool, 6 in West Ham, and 5 each in Willesden and Sheffield The fatal cases of measles, which had been 84, 100 and 81 in the three preceding weeks, further fell to 75, the highest annual death rates from this disease were 1 4 in Bristol, 1 7 in Exeter and Stockport, and 2 5 in Leicester The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 68, 80 and 73 in the three preceding weeks, further fell to 60 and included 20 in London and 4 each in Manchester and Middlesbrough The deaths referred to scarlet fever, which had been 28 22, and 30 in the three preceding weeks, fell to 23, of which 7 occurred in London and 2 in Stoke-on Trent The fatal cases of enteric fever, which had been 9, 14, and 10 in the three preceding weeks, numbered 9, and included 3 in London and 2 in Tynemouth

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2462 2464 and 2325 at the end of the three preceding weeks fell to 2224 on Saturday last; 244 new cases were admitted during the week against 206 254, and 225 in the three preceding weeks These hospitals also contained on Saturday last 1476 cases of diphtheria, 59 of enteric fever 59 of measles, and 14 of whooping-cough, but not one of small pox. The 1161 deaths from all causes in London were 8 in excess of the number in the previous week and corresponded to an annual death rate of 13 4 per 1000 The deaths referred to diseases of the respiratory system, which had been 329, 346 and 246 in the three preceding weeks, rose to 264 in the week under notice, but were 208 below the number registered in the corresponding week of last year

Of the 4850 deaths from all causes in the 96 towns, 183 resulted from different forms of violence and 395 were the subject of coroners' inquests, while 1394 occurred in public institutions The causes of 37, or 0 8 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in Sheffield, Leeds, Bristol Bradford, Hull, and in 73 other smaller towns Of the 37 uncertified causes, 8 were registered in Birmingham, 6 in Liverpool 3 each in Manchester and Tynemouth, and 2 each in Bootle, Preston, and Gateshead

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2 355 300 persons at the middle of this year 1091 births and 696 deaths were registered during the week ended Saturday, Jan 15th The annual rate of mortality in these towns, which had been 17·0, 17·4 and 15·9 per 1000 in the three preceding weeks fell to 15·4 per 1000 in the week under notice During the 13 weeks of last quarter the mean annual death rate in these towns averaged 17·9 against a corresponding rate of 15 5 per 1000 in the large English towns The death rate during the week ranged from 6 2 in Motherwell 9 1 in Clydebank, and 12 7 in Leith to 19 5 in Coatbridge 21·5 in Greenock, and 22·9 in Kirkcaldy

The 696 deaths from all causes were 23 fewer than the number in the previous week, and included 66 which were referred to the principal epidemic diseases, against 74 and 72 in the two preceding weeks Of these 66 deaths 23 resulted from measles, 13 each from diphtheria and infantile diarrhœal diseases, 11 from scarlet fever 5 from whooping-cough, and 1 from enteric fever, but not one from small pox The annual death rate from these diseases was equal to 1 5, against a corresponding rate of 1 0 per 1000 in the large English towns The deaths attributed to measles, which had been 16, 26, and 17 in the three preceding weeks, rose to 23, and included 7 in Glasgow, 6 in Greenock, 4 in Edinburgh, and 3 in Hamilton The deaths referred to diphtheria, which had been 8, 11, and 19 in the three preceding weeks, fell to 13, of which 5 were registered in Glasgow, 3 in Edinburgh, and 2 in Paisley The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 11, 11, and 10 in the three preceding weeks, rose to 13, and included 7 in Glasgow The deaths attributed to scarlet fever, which had been 12, 21, and 18 in the three preceding weeks, fell to 11, and comprised 7 in Glasgow, 3 in Edinburgh, and 1 in Paisley Of the 5 deaths from whooping-cough, which were slightly in excess of the average in recent weeks, 3 were registered in Glasgow The fatal case of enteric fever was recorded in Edinburgh

The deaths referred to diseases of the respiratory system, which had declined from 322 to 139 in the seven preceding weeks, further fell to 114 in the week under notice, and were 161 below the number registered in the corresponding week of last year The deaths from violence numbered 33, against 32 and 42 in the two preceding weeks

HEALTH OF IRISH TOWNS

In the 19 town districts of Ireland, with populations exceeding 10,000 persons at the last Census, 573 births and 463 deaths were registered during the week ended Saturday, Jan 8th The annual rate of mortality in these towns, which had been 22 4, 17 3, and 24 2 per 1000 in the three preceding weeks fell in the week under notice to 21·0 per 1000 of their aggregate population estimated at 1,148,468 persons at the middle of last year During the week the death rate was equal to 20 3 in Dublin (against 13 3 in London and 15·0 in Glasgow), 19 8 in Belfast, 25 8 in Cork, 20 2 in Londonderry, 17 6 in Limerick, and 49 4 in Waterford, while in the 13 smaller towns the mean death rate was 19 8 per 1000

The 463 deaths from all causes were 71 fewer than in the previous week, and included 29 which were referred to the principal epidemic diseases, against 37 and 59 in the two preceding weeks Of these 29 deaths, 9 resulted from measles, 8 from infantile diarrhœal diseases, 4 each from scarlet fever and whooping cough, 3 from diphtheria, and 1 from enteric fever, but not one from small pox The mean annual death rate from these diseases was equal to 1 3, against corresponding rates of 0 9 and 1 6 per 1000 in the English and Scotch towns respectively The deaths attributed to measles, which had been 18, 19 and 23 in the three preceding weeks fell to 9, and comprised 5 in Dublin, 3 in Belfast, and 1 in Cork The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 9, 8, and 9 in the three preceding weeks, numbered 8 of which 3 were recorded in Belfast and 2 in Dublin The fatal cases of whooping-cough, which had been 8, 4, and 12 in the three preceding weeks, fell to 4, and included 2 in Belfast The deaths attributed to scarlet fever, which had been 7, 3, and 9 in the three preceding weeks, declined to 4, and comprised 3 in Belfast and 1 in Dublin The 3 fatal cases of diphtheria, of which 2 were registered in Dublin and 1 in Belfast, were equal to the average in the three preceding weeks The death from enteric fever was registered in Waterford

The deaths referred to diseases of the respiratory system, which had been 116, 92, and 147 in the three preceding weeks, fell to 114 in the week under notice, and were 51 below the number registered in the corresponding week of last year Of the 463 deaths from all causes, 145, or 31 per cent, occurred in public institutions, and 15 resulted from different forms of violence The causes of 16, or 3 5 per cent, of the total deaths, were not certified either by a registered medical practitioner or by a coroner after inquest in the large English towns the proportion of uncertified causes did not exceed 0·9 per cent

---

LECTURES ON MILK, ITS SUPPLY AND DISTRIBUTION —Commencing on Jan 20th a course of ten lectures on these subjects will be given at the South Western Polytechnic Institute Manresa road Chelsea The lectures which will be given on successive Thursday evenings at 7 30 P M have been arranged for those engaged in the milk trade or in institutions where milk is largely consumed, and for sanitary and food inspectors A practical class for simple laboratory work will be held immediately after the lectures

FUNCTIONAL NERVOUS DISEASE

To the Editor of THE LANCET

SIR,—In your issue of Jan 15th under the above heading there is a letter of very great significance from Dr C A Mercier criticising the so called method of psycho analysis, which has taken the place of the older method of observation and induction, hitherto called psychological analysis, the assumed utility of the former claiming for it the fresh title of the "new psychiatry" Those whose lives have been devoted to the investigation of nervous and mental disorders have attributed the causes of these pathological conditions to lie among the factors of heredity, environment, education, fatigue, and various toxins generated from within or introduced from without, but they have not excluded the disturbing effects of strong emotion, grief, anxiety, worry, or any moral shock

The school of psycho analysis introduced by Freud has depicted man as a beast or animal dominated by crude instincts and base passions—a natural corollary to the teachings of Nietsche, Treitschke, and Bernhardi—and their set purpose is to discover some unpleasantly painful or shameful event in the past history of the patient because these are taken to be the root cause of most cases of mental perversion, and also because sexual matters are looked upon as the bedrock of most cases of insanity This hypothesis is not only unjustifiable but unproven, and it is moreover, an insult to the clean mind of an innocent sufferer, and I join in the strong remonstrance so ably put forward by Dr Mercier, who is a mental physician, a physiologist, and psychologist of the highest standing In season and out of season Dr Mercier has called attention in the public press and elsewhere to the gross injury caused to the patient by the practices of this school designated as the "new psychiatry I can quote from personal experience the actual damage done by the psycho analyst through suggestions made of lewd, objectionable, and bestial thoughts to the moral feelings of an unsuspecting mind I fully admit that much has been done by some psychologists to elucidate facts in the unconscious field, but I question whether one single case has ever recovered through psycho analysis It is within the knowledge of every practising physician that certain sensations or experiences are able to determine certain attitudes of mind after the memories of the former had faded, and the hypothesis that the memories of past experiences are potential agencies in determining certain abnormal mental states is an acknowledged truth, but it is not proved that these are based upon "sexual traumata,' whatever this may mean

I speak with some authority as a teacher of mental diseases in one of the largest metropolitan schools of medicine, as a former examiner in the subject at the London University, and as the resident physician of one of the largest asylums in this country, and I have no hesitation in affirming that the practice of the psycho analysts should be repressed with all the strength and force of a controlling hierarchy—if such there be ' As has been truly said, "a diagnosis in the Freudian sense is a diagnosis of the mind that made it" I am not in sympathy with much that has been said recently by English followers of Freudism, and it is satisfactory to know that for some time past the chief exponent of this doctrine in Europe, K. Jung, of Zurich, has broken with the school upon certain points

I repeat, from my own practical experience and knowledge of the effects of psycho analysis upon those among whom the craft is practised, that in so far as it is a probing for hidden and forgotten sexual occurrences, it is repulsive and disreputable, ethically objectionable and deserving of the strongest condemnation

I am, Sir, yours faithfully,
ROBERT ARMSTRONG JONES, M D Lond

Claybury Jan 19th 1916

SHRAPNEL WOUNDS

To the Editor of THE LANCET

SIR,—A large number of injuries caused by shell fire are now very generally described as "shrapnel wounds," and this would appear to be a curiously erroneous description The shrapnel shell, called after its inventor, Lieutenant, afterwards Lieutenant General, Shrapnel, Royal Artillery, and brought into the service in 1803, is a projectile in which a small bursting charge opens the shell and liberates the bullets with which it is packed In its present form it takes the shape of the ordinary elongated projectile, and consists of a thin steel casing, in the base of which is a small charge of black powder At the upper end, and partially forming the coned top, is a time and percussion fuse, the flash from which is communicated to the bursting charge by a tube passing down the interior of the shell Round this tube are packed spherical bullets of lead hardened with antimony, and varying in number and weight with the calibre of the gun, the interstices being filled in with resin poured in in the melted state Before firing the time arrangement of the fuse is so set as to ensure the burst taking place at the most effective distance short of and above the objective. On the ignition of the bursting charge the fuse is blown out, together with the coned top of the shell, the latter being only lightly attached to the body, and the bullets thus liberated fly forward in a cone with the velocity that the shell then has, the steel body travelling on intact Should the time arrangement be set too long, the percussion part of the fuse ensures the shell opening on impact, but to be effective against troops in the open the shell should burst in the air From the above it will be seen that shrapnel shells have practically no fragments, and distribute no splinters

As an illustration of the fact that the word shrapnel is commonly used to express fragments or *mitraille*, I may say that when pointing out to a police inspector how much damage had been done to the walls and doors by the stones in the reinforced concrete floor, in a building in which a Zeppelin bomb had fallen, he said, "Yes, sir, bits of shrapnel I now find that this misuse of the word has become general and that wounds obviously inflicted by the sharp, jagged splinters of a high explosive common shell are described as shrapnel wounds whereas those caused by shrapnel bullets are always—and rightly—classed among bullet wounds There are both in our service and in that of the enemy a few high explosive shrapnel which do break up and distribute splinters but the fuse for these is so complicated since this projectile is meant to serve both purposes—i.e, the ordinary and the high explosive shell—that its use is very limited We may say, then, that the so called shrapnel wounds are invariably wrongly described, as this projectile is the only one which, on the explosion of its bursting, or more properly opening, charge does not distribute splinters

I am, Sir, yours faithfully,
DESMOND O CALLAGHAN,
Major-General.

Jan. 18th 1916

A CASE OF MASKED MALARIA

To the Editor of THE LANCET

SIR,—Mosquitoes are common in Accra, especially in the native quarter, those of the genus Stegomyia being most frequently met with. Anophelines, though less common, are also seen In the European residential quarter, however, where sanitary measures are more under control, it is the exception to find anopheles or, in fact, any type of mosquito Despite this fact, malarial fever amongst the European population is often met with, the prevalent type being subtertian The following is a case in point

The patient, a European aged 33 years arrived in the Colony early in August, 1914 For the first two months he was engaged in work which took him to Lome (Togoland) and to Duala (Cameroons) At these places he was severely bitten by mosquitoes On his return to the Gold Coast he was stationed in Accra The patient was addicted to alcohol, and would consume "the best part of a bottle of whisky a day" Quinine was taken very irregularly Two months previous to the date of his admission to hospital he began to complain of feeling "off colour," vomited occasionally, and had irregular slight rises of temperature Only on one occasion prior to admission was he so ill as to necessitate his absence from duty for two days He also suffered from insomnia, but this did not react upon his health in any appreciable way, he was throughout active and cheerful.

On August 21st, 1915, he was admitted to the Accra Hospital, and I am indebted to the senior medical officer in charge, Dr J H Collier, for the clinical notes

On admission there was no fever, but the patient vomited once or twice Two thin blood films were at once sent to the laboratory for examination this being the routine procedure Young ring forms of P falciparum were found in fair numbers averaging 5 in a high power field A differential count gave the following percentage readings polymorphonuclears 48, large mononuclears 14, lymphocytes, 35, and basophiles 2 Vomiting ceased the day after admission and the patient was practically well On Sept 3rd another examination of his blood showed numbers of subtertian gametocytes (crescents), one crescent in eight fields, and the differential count was polymorphonuclears 55 per cent, large mononuclears 12, and lymphocytes 33, with marked leucopenia The temperature remained subnormal, and the patient continued to show no clinical indication of the malarial infection in his blood During his stay in hospital he received 5 grains of quinine daily

The outstanding features of this rather unusual case are 1 The total absence of fever and other symptoms of a malarial infection, notwithstanding the heavy infection of the patient s blood and the proved activity of the parasites, as evidenced by their progressive development from rings to crescents 2 The marked leucopenia and the absence of any sign of phagocytosis 3 The large number of crescents in the peripheral circulation, a rather unusual occurrence for it is generally held that, owing to their tendency to clump, these forms are frequently arrested in the finer capillaries of the internal organs, spleen, brain, &c, and that it is by virtue of this property that the pernicious symptoms of a subtertian infection are brought about

In his "Prevention of Malaria," under the heading of "The Appearance of Sexual Forms," Sir Ronald Ross states —

> The malignant gametids begin to appear about a week after the onset of the fever, and may remain circulating in the blood for several weeks We do not know what determines their appearance, but the asexual forms and the fever frequently vanish when they appear

Again, under the heading "The Parasites during the Rallies," the same writer states —

> In the rallies between relapses, few sporids frequently none at all, can be discovered, though gametids which do not seem to produce fever may still abound

Here, then, is a partial explanation of the absence of fever in this case, the cause of the absence of fever at a time when sporids were in abundance is, however, not very evident

Finally, under the heading "Probable Causes of Rallies and Relapses" Sir Ronald Ross states —

> Cases are often reported in which the patient during relapses suffers from malaise dyspepsia and so on, rather than fever, although parasites are numerous enough to be found In such, I presume, the antitoxic power of the blood has become better developed than the germicidal power

Herein perhaps lies the second half of the explanation of this case, though one is tempted to ask what determines the development of the antitoxic power of the blood at the expense of the germicidal power? If we assume that the absence of fever and of the usual clinical manifestations of malaria is the result of antitoxin sufficiency then the patient in this case was well protected. If, on the other hand, the presence of fever is an index of reaction to infection on the part of the body, and a phenomenon in the course of phagocytosis and bacteriolysis, then, in the absence of evidence of reaction, we must assume that despite his appearance of well being, the patient was, or would soon be, in a dangerous condition, one perhaps in which the slightest determining cause would precipitate pernicious symptoms, such as coma or blackwater fever Had the amount of alcohol taken, by virtue of its vaso dilator effect on the peripheral vessels and its depressant effect on the thermogenetic centre, any bearing on the case, and is not the presence of a large number of crescents in the peripheral circulation and the absence of fever to be thus explained? Personally I am inclined to the opinion that the case was one in which the symptoms of malaria had been masked by alcohol, and it seems to me that "masked" malaria, as distinguished from "latent" malaria, may be brought about by influences other than alcohol, and that such a condition frequently precedes an attack of blackwater fever, though of course in these cases the blood infection may not be so evident —I am, Sir, yours faithfully,

ILLUMINATION IN OPERATIONS

To the Editor of THE LANCET

SIR,—After experimenting with ceiling lamps distributed in various positions, the writer has found the following arrangement to be very satisfactory and has used it in his theatre for the last three years Four electric lamps, each of 60 candle power and enclosed in elongated glass globes, are attached to the ceiling, which is 13 feet above the floor The lamps are arranged 1½ feet apart, in a single row above the operation table in its long axis and give a brilliant light remarkably free from shadows The glass globes are watertight and allow of the ceiling being hosed with the rest of the theatre For operating at the bottom of long and narrow cavities either a reflected light or a small lamp of the cystoscope type inserted in the cavity is usually essential

For operations performed in daylight a theatre with a south, rather than the usual north, aspect has considerable advantages, which include an excellent light, even on dull days, and a natural warmth which minimises the amount of artificial heating required —I am, Sir, yours faithfully,

Plymouth Jan 12th 1916 C HAMILTON WHITEFORD

LOSS OF SPEECH AND SHELL-SHOCK

To the Editor of THE LANCET

SIR,—During my 22 years' service in the army I can recall five cases of men having been brought to hospital suffering from sudden loss of speech due to shock I found they were all cases of malingering and recovered their voice under an anæsthetic Ether is the anæsthetic to give, and it is well to keep the patient under it for half an hour, and he will have plenty to say when he recovers —I am, Sir, yours faithfully,

J McLAUGHLIN, M D
Lieutenant-Colonel (late) R A.M C

THE PREPARATION OF CATGUT BY PICRIC ACID AND OIL OF CLOVES

To the Editor of THE LANCET

SIR,—The method of preparing catgut suggested by Roeder is very simple and inexpensive The raw gut is placed in a saturated solution of picric acid in oil of cloves for one week, rinsed thoroughly for about ten seconds in sterile water or a 1/5000 bichloride solution to remove the oil globules clinging to the surface, and then stored in 95 per cent alcohol In four days it is ready for use Before placing the gut in the saturated solution of picric acid and oil of cloves I prefer to formalise it in a 5 per cent solution for 24 hours, this modification undoubtedly gives the gut additional strength and keeps it from swelling The acid and the oil both being soluble in alcohol are extracted to a considerable extent from the catgut, rendering the suture unirritating to the tissues

The advantages claimed for the method are these The gut is rendered absolutely sterile throughout, as the picric acid and oil of cloves have marked penetrating powers The oil of cloves, besides being a powerful germicide, renders the gut pliable very strong, and less quickly absorbed, and, further, the gut does not deteriorate with storage I have used the slightly modified Roeder method of preparation for some months with gratifying results, and can recommend it with confidence as one of the best for the preparation and sterilisation of catgut

I am, Sir yours faithfully

CANCER AND HEREDITY

To the Editor of THE LANCET

SIR,—Though an isolated case in the experience of one individual be of dubious value the collation of such instances may be of some importance With the latter object in view I venture to bring to your notice the following family history with which I have recently become acquainted

A had six brothers, four of these married, all dying without issue A himself died at the age of 36 from pyloric cancer He had three daughters and five sons The eldest, a daughter (B) died, unmarried, from carcinoma mammæ Five of his children married, two died childless, the eldest son had one child, a girl, who died young, a daughter married twice, having one child by each husband, and both died young Another son (C) died, aged 67, from cancer of the bowel, his wife's mother and sister, as well as an old servant who lived with them, all died from cancer in the same house Another son has two children, the only representatives of the third generation, and the father in law of one of these died from cancer

It would seem almost as though the *vis medicatrix naturæ* were applied in this family to suppress it, for three members of it have died from cancer, six are childless, and two others who have married into other families with a history of cancer are also childless A comparable case is recorded in the *Gazette des Hôpitaux* for May, 1914 This refers to an officer of the First Empire who died from cancer of the stomach cancer appeared in the two succeeding generations of his descendants These may be coincidence, but abundant coincidences form a law

I am, Sir, yours faithfully,

Farnborough Jan 16th 1916 JAMES RAE

Obituary

GUIDO BACCELLI

THE "Third Italy' has just lost one of its creators in the veteran clinical teacher and consultant who was revered throughout its borders as typical of the forces, moral as well as combatant, that inspired and promoted that "Risorgimento '

Born in Rome on Nov 25th, 1832, Guido Baccelli possessed a hereditary love of the medical art and began his preliminary studies in the Ghislieri College at Pavia in the early forties of the century Those were the days when Italy was agitated "from the Alps to Etna' with the yearning for freedom and unity, and young Baccelli was among the keenest in the patriotic ranks He ran away from college to enrol among the volunteers and was with difficulty brought back to his studies At the end of the scholastic years indeed he joined the Garibaldini in the defence of Rome against the French till at the close of that heroic but abortive struggle he had to fly the city as an exile That was in the early summer of 1849 and then began those medical studies which were ever after the ruling passion of his life Having graduated with great distinction at the Sapienza, he was, when little over 24 years of age, elected to the chair of Legal Medicine from which after a brilliant discharge of its duties he passed to the professorship of Pathological Anatomy and thereafter to that of Clinical Medicine a post which he never abandoned An admired and diligent student of the great Morgagni he translated and edited the works of that pioneer and followed up his researches on cognate lines corresponding with contemporary German pathologists Leube in particular and introducing while developing their findings in the Roman school He devised methods of diagnosis in thoracic diseases which after their soundness had been confirmed in his own clinique were adopted in other schools, transalpine as well as Italian, and he devoted special study to malarial fever, in connexion with which he published a treatise on the spleen, and drew attention to the phenomena of the 'malaria perniciosa" and the form which he designated "subcontinua." In therapeutics he was among the first to practise intravenous injections of mercury in syphilis, while his experiments in treating traumatic tetanus by the intravenous injection of phenic acid, initiated in 1901, have gradually found acceptance, and in the war now raging on the North Eastern frontier the method is reported to have proved highly successful

With all this varied work he never lost touch with his country's general progress, particularly was he interested in the all important sphere of education With well nigh half of her population unable to read or write, Italy possesses 23 universities, each duchy, archduchy, or kingdom absorbed into her unity having contributed one or more of these "seats of learning" Graduation thus cheapened and utilised, the country became inundated with briefless barristers and practitioners without patients, so as to create that most dangerous of all classes, the "educated unemployed" Having, after his return for a Roman constituency, become Minister of Public Instruction, Baccelli's chief concern was to reduce this plethora of degree giving schools and retain only four, whose efficiency would be ensured by better emoluments for the professoriate, and whose degrees could be accepted as adequate to modern standards Under the present system, he said, "we are creating an 'academic proletariat,' which is responsible for much of the agitation, political and social, which has proved a real hindrance to the country's development" The speech in which he introduced his proposed reform was one of the most memorable ever heard at Montecitorio—a specimen of the finished oratory which he could always command on critical occasions But the short-lived Ministeries in which he held the portfolio left no time for the carrying out of his reforms, and Italy remains, to her own disadvantage, a victim to what he termed "academic hypertrophy" A brief tenure of the Ministry of Agriculture gave him another opportunity of introducing salutary innovations—the reclamation or "bonifica" of the Roman Campagna, but it was always in his control of public instruction that he achieved, wherever practicable, the most conspicuous results An accomplished classical scholar, able indeed on the spur of the moment (as at the Berlin International Congress of Medicine in 1890) to deliver an address in the Latin tongue which from its clear intonation, assisted by attitude and gesture, was wonderfully intelligible and impressive, he took the deepest interest in archæological research, and, aided by the Cavaliere Rodolfo Lanciani, he excavated the Hall of the Vestals and brought to light in the Forum not a few monuments which solve many problems, historic and other, long prolific only of barren discussion

But these undertakings were by works to his main programme, which was to rehabilitate his compatriots, physically, morally, and intellectually, and he laboured throughout his life to develop and to make ever more efficacious the science and art of medicine His crowning effort in this direction was his founding the great hospital of the Policlinico which remains a monument not only of his enlightened acceptance of wholesome suggestions from the outside world, but of that catholicity characteristic of true science which does honour to coadjutors and pioneers whatever their nationality It was this spirit which won for him reciprocal acknowledgment throughout the academic world, corresponding member, or honorary fellow, as he was, of innumerable scientific bodies, medical and other, throughout the two hemispheres His loss to Italy is only less than his loss to the republic of learning, as the condolences which have poured in on his family from far and near abundantly testify At all the medical schools in Italy *oraisons funèbres* have been delivered from the professorial chairs to culminate in that national demonstration of mourning, the State funeral in the Campo Santo of Rome

CHARLES HENRY FOX, M D St AND, F R C P EDIN, M.R C S ENG

THE death of Dr Charles Henry Fox on Dec 25th last, in his seventy ninth year, will recall to alienists the work carried on by the Fox family at Brislington House Asylum, Somerset, for the greater part of the last century, and removes from our midst the sole medical representative of a distinguished family of physicians

Dr Fox was born on June 7th, 1837, at Brislington House, and was the fourth son of Dr Francis Ker Fox, of Brislington House Asylum, and brother of the late Dr Edward Long Fox, of Clifton, Bristol Educated at Shrewsbury, he entered as a student at St George's Hospital in 1855 After taking the diploma of the Royal College of Surgeons of England he went for certain classes to Edinburgh, and in 1860 graduated in medicine at St Andrews The following year he joined his father at Brislington House Asylum, and remained there until 1894 in partnership at first with his father and then with his half brother, Dr Bonville Bradley Fox He retired from practice in 1894 and went to live at Edinburgh, which he chose as his place of residence from his pleasant memories of earlier student life, and where he had many old and valued friends His health became seriously impaired 12 years ago, and for the last few years he had become completely invalided Yet almost to the day of his death he took a keen interest in subjects of which he made a hobby, and preserved his genial disposition and bright conversational powers

NORTHCOTE WILLIAM SPICER, M R C S, L S A

MR N W Spicer died recently at his residence, Chard, Somerset, in his eighty sixth year The deceased was born in Chard, where his father was a well known surgeon He received his medical education at St Bartholomew's Hospital, taking the "College and Hall" in 1853 and 1854 respectively He shortly afterwards joined his father at Chard, and for many years had the leading practice in the district and held the principal medical appointments He was a great supporter of the local hunts, being for a long time honorary secretary to the Cotley Hunt, and was also a frequent follower of the Taunton Vale and the Blackmore Vale Hunts He was for several years president of the Chard Constitutional Club Mr Spicer was highly esteemed and respected in Chard, where he took an interest in all local matters and by his death the profession has lost a much respected representative

THE LATE SIR FREDERIC HEWITT

WE have received many communications, some intended for publication and some not, from friends of the late Sir Frederic Hewitt, deploring his death.

Mr W J McCardie writes —

I wish to add to your notice in THE LANCET of last week a few words of appreciation of my friend the late Sir Frederic Hewitt, whom for many years I have held in honour as a man and in the highest esteem as an anæsthetist His example has stimulated many an earnest follower, and personally I can never forget what I owe to him A simple minded man ever ready to fairly discuss problems in anæsthesia, he was yet strong in his convictions, and would face any opposition even though he were one alone opposed to the views of a large meeting He thought it his duty to agitate for legislation to prevent unqualified practice of anæsthesia, and gave up much of his valuable time in advocating his cause His insistent work for reform in anæsthetics will soon, it is to be hoped, bear full fruit His original and practical work, writings and suggestions in most departments of anæsthesia marked him a master of his art and as the leader among anæsthetists of his time, and he was so regarded throughout the English speaking world He had a natural gift for bringing confidence to patients and producing anæsthesia of the best type He was always evolving some new idea and working it out with his well known thoroughness and perseverance His book on "Anæsthetics and their Administration" is a record of his observations, and is replete with detailed practical and helpful information such as the anæsthetist can hardly get elsewhere I mourn the premature loss of a great-hearted friend and a leader among anæsthetists whose status he did so much to improve His influence will long last

Mr Bellamy Gardner writes —

The powerful influence of Hewitt s judgment and will upon the course of medical practice and opinion, as well as his untiring labours for the advancement of the science and art of surgical anæsthesia have ceased, but his written words remain to remind us of his extraordinary accuracy, assiduous attention to detail and high appreciation of all the responsibilities of medicine He was distinguished for his courage and capacity

Mr John Cahill expresses more particularly the feeling of St George s men in the loss which they have sustained He writes —

To one who has watched his unfailing devotion to his work, from the days of studentship and house officer all through a career of painstaking and deliberate toil culminating in the highest position in an important specialty it seems a marvel that Hewitt should have found the time and energy to maintain in so many and diverse directions the personal intimacy which was his ideal of social life Yet Hewitt was the man who made the social undertakings of his circle a success by his unfailing tact and foresight repeatedly bringing together the friends who would otherwise have drifted apart from himself and from each other In the later and more ample years of successful was at Hewitt s hospitable table that you met the mutual friend whom you might not have seen for half a life time Within recent years it was he who breathed new life into the Students Club of his old medical school bringing into one social organism the scattered units of which it was composed and associating the students of former years with the rising generation of the day The circumstances of his return comparatively late in life to take up a position on the staff of St George s Hospital form a characteristic proof of the value which Hewitt attached to all old friendships and all associations It was at other hospitals that he had been given the opportunities which he had turned to such good account He was then at the zenith of his career and there was no professional or personal advantage to be gained by taking on the fresh duties of the appointment which was offered to him But the assurance that he was wanted by his old hospital and school sufficed to induce his acceptance of the additional burden How loyally and wholeheartedly he responded to the call then made upon him is known to his colleagues and to the governing body of that hospital

The War

THE CASUALTY LIST

THE following names of medical men appear among the casualties announced since our last issue —

Wounded

Lieutenant N S Joshi, I M.S
Captain J A Sinton I M S
Lieutenant Colonel W Ransom, R.A.M C, attached to the 3rd Northumbrian Field Ambulance (T F)
Captain H. S Milne, R A.M C

THE HONOURS LIST

The following promotions and appointments of medical officers are announced —

For Services Rendered in Connexion with the War

To be C B (Military Division) additional Member

Russell Col (temp Surg Gen.) M W., Deputy Director Gen., A.M S

For Services Rendered in Connexion with Military Operations in the Field

To be C B (Military Division) additional Members

Ford Surg-Gen. R W DSO

Indian Subordinate Medical Department

Awarded the Second Class of the Indian Order of Merit

Ram Singh, 862, 1st Cl. Sub-Asst Surg (attd 1-5th Gurkha Rifles)
Pargan Singh, 1250 2nd Cl Sub-Asst Surg (attd 6th Jat Light Infantry)

Awarded the Indian Distinguished Service Medal

Pheo Ram 772, 1st Cl Sub-Asst. Surg (attd 1-5th Gurkha Rifles)
Kishan Singh 12-5 2nd Cl Sub-Asst Surg (attd 112th Indian Field Amb.)
Mathuraparshad Sarwal 1350 3rd Cl Sub-Asst Surg (attd 57th Wilde's Rifles, Frontier Force)

By an oversight, which we regret, the name of Dr A W J MacFadden, Chief Inspector of Foods, Local Government Board, was omitted from the list published in THE LANCET of Jan 1st of those who were appointed Companions of the Bath in recognition of services rendered in connexion with the war

DEATHS AMONG THE SONS OF MEDICAL MEN

The following son of a medical man must be added to our lists of those who have fallen during the war —

Second Lieutenant O P Gwynne 92nd Punjabis, younger son of the late Dr C N Gwynne, of Sheffield

THE MEDICAL EXAMINATION OF RECRUITS

The duty of a medical recruiting officer is at no time an easy one He is aware that it is hoped that he will pass a large number of candidates but that the admission of bad lives will be rightly resented, and he is at the same time offered a fee which does not conform well with the time occupied and the responsibility incurred Recently the position was made still harder by the sheer bulk of the material he had to cope with and, if we have been correctly informed, by other difficulties of an entirely avoidable nature As the work of recruiting medical officers seems to be by no means at an end, but, on the contrary, to be entering on a new and more responsible phase, it may serve a useful purpose to state some of the difficulties to which reference is made Medical officers have been required not merely to examine as many as 250 men at a single depôt, but to do a daily round of five or more such centres Instead of finding every facility provided for his work, the medical recruiting officer has sometimes had to suffer from insufficient accommodation, a frequent change of orderlies, pressure from the combatant officers to enlist unfit men and overlook weaknesses, and collusion to deceive between recruits and recruiters The blame must, of course, not entirely be laid on the recruiters, inasmuch as the men examined were volunteers anxious to join and naturally prone to use every means at their disposal to conceal any ailment likely to cause their rejection But less creditable forms of deception have been reported, especially in regard to the sight test, by recruiters and orderlies, with the aim of securing the grant Such methods can only bring discredit on the recruiter, and a risk of early breakdown to the recruit

It is therefore no small satisfaction to receive an official intimation that all these drawbacks have now been remedied for the future in a scheme elaborated by the Director General of the Army Medical Service, which came into force on Jan 18th Examining stations are to be set up, of which 98 are actually in readiness, each under the control of a medical board with an officer, active or retired, of the Royal Army Medical Corps presiding The number of recruits examined per day at any one station is not to exceed 200, and this number will be well within the compass of the medical examiners Each recruit is to be carefully examined in a quiet room and then classified according to his capacity These data will be handed on to the military authorities and dealt with by them according to military requirements No man will be sent to any work for which the medical board has considered him unfit In doubtful cases the decision may be referred to expert opinion Eyesight tests have always been framed with special regard to military efficiency and are not primarily medical standards The work of translating the military requirement as regards eyesight into actual tests was entrusted to the Ophthalmological Society by the Director General, and these tests are the basis of acceptance or rejection in the case of each recruit examined As far as possible an ophthalmic surgeon will be a member of each medical board

---

THE PROPOSAL FOR A COLLEGE OF NURSING

At a special conference of the Society for the State Registration of Nurses called for the purpose of considering the proposal for a College of Nursing put forward by the Joint War Committee of the British Red Cross Society and the Order of St Joh of Jerusalem (see THE LANCET, Jan 8th, 191 p 109) a resolution was unanimously pass stating that the proposed scheme was "dangerou to the best interests of the profession of nursing and agreeing to oppose the proposal and to pus forward the demand for legal registration

---

CENTRAL MEDICAL WAR COMMITTEE THE ENROLMENT LETTER

The following has been addressed by the Centr Medical War Committee to every practitioner o military age in England and Wales who has no accepted a commission in the Royal Army Medica Corps —

DEAR SIR —You are no doubt aware through th columns of the medical journals and the agency of yo Local Medical War Committee of the plan of the Centr Medical War Committee for enrolling all medical men o military age for service if and when required in the R A M C or the Medical Service of the Royal Navy

The end of the war is not yet in sight The country i greatly increasing its army, and Lord Derby's scheme ha provided an immense number of potential soldiers who wil be drawn upon as required It is clear, therefore, that man more medical officers will be wanted, and members of o profession will, we are convinced, be at least as alive to th military necessities of the country as other members of th community

Medical practitioners were not expected to attest unde Lord Derby's scheme because it was recognised that the could better be dealt with by a Committee representative of their profession

The Central Medical War Committee, originated by th British Medical Association, but including members wh do not belong to the Association is working with th full consent and authority of the Director General of the Army Medical Service The Committee is recognised by him as the medium for providing medical men needed by the Wa Office for the Army, and at the same time protecting th needs of the civil population

The Central Medical War Committee now confidently appeals to you as a medical man of military age to assist our national military organisation by enrolling yourself for service in the R A M C when required and to justify the confidence placed in the profession, which has been asked to organise itself for the service of the country To enable you to do this we enclose Forms W 7 and W 8 which should be completed and returned to this office with as little delay as possible.

The Committee hopes to enrol every medical man of military age (in the case of our profession up to the age of 45) so that as further calls are made by the Director General of the Army Medical Service these calls may be promptly met with due regard to the necessity of the services, to the needs of the civilian population, and to the circumstances of individual medical practitioners Unless all are enrolled it will be very difficult for the Central Medical War Committee to make its calls throughout England and Wales in a manner which will minimise the inconvenience suffered both by the community and by individual medical practitioners

It must be remembered that the enrolment of all medical men of military age does not mean that all enrolled will be called upon to take a commission The number called upon will depend entirely on the demands of the services The calls will be made in consultation with the Local Committees and due regard will be given to (1) the system of classification adopted as a guide by the Central Medical War Committee (see Appendix A), (2) the circumstances of the individual practitioners, and (3) the opinion of the Local Medical War Committees as to which practitioners can be most easily spared The Local Committee will advise and coöperate with a view to safeguarding the work and interests of th absent practitioners so far as it is able

The Central Medical War Committee hopes that all practitioners to whom this is addressed will believe that some months experience in dealing with this question has made the Committee thoroughly conversant and deeply sympathetic with the difficulties which most practitioners experience in leaving their work But some thousands of medical men have now made the sacrifice and what they have done others may fairly be asked to do. The Committee believes also that those who are not able, or are not required, to undertake military service will so far as opportunity offers and their ability permits contribute to the military strength of the country by placing their services at the disposal of the Local Medical War Committees for the purpose of arrangements that may be necessary for the conservation of the practices of men of military age to enable them more easily to enrol.

On enrolment you will receive a numbered certificate and this will be taken as equivalent—so far as the medical profession is concerned—to attestation under Lord Derby's scheme. If you have been attested under that scheme you should at once enrol with this Committee. Your attention is drawn to the official communiqué issued by the Army Council on Jan. 13th, 1916 (see Appendix B).

It is to be specially noted that one great privilege is given to the medical profession that does not apply to any other section of the community, namely, that a medical man can enter the R.A.M.C. on a contract for one year's service, whereas everyone else must join the services for the duration of the war. It cannot be assumed, however, that the same privilege will be accorded to those practitioners who fail to enrol with our Committee.

It has been urged frequently that the Army does not require so many medical officers as are now being requisitioned. On this point we would impress upon you that at present no one is in a position to say how many medical officers may be required; that we are in close communication with the War Office; that the question of economy of personnel is continually under discussion and rearrangements are continually being made to obtain the most economical service. We are convinced that the War Office, the Local Government Board, and the National Health Insurance Commissioners, as well as this Committee, are fully alive to the needs of the civilian population and are doing their utmost to adjust the requirements of the military and civilian medical services to the existing conditions.

We are, yours faithfully,

N. BISHOP HARMAN, } *Secretaries.*
ALFRED COX,

[ENCLOSURES.]

W 7.

As Appendix A to this letter there is added the system of classification under which it is proposed that medical men should be called up for service (*vide* THE LANCET, Dec. 11th, 1915, p. 1321), and as Appendix B the communiqué issued by the Army Council on Jan. 13th, 1916, explaining the position of the Central Medical War Committee with regard to enrolment (*vide* THE LANCET, Jan. 15th, 1916, p. 163).

We have received from a well-informed correspondent a criticism of a statement made in THE LANCET of Dec. 11th that the Local Government Board were in general agreement with the memorandum brought forward by the Central Medical War Committee. The statement went beyond the facts, as it would seem to imply that the Local Government Board had expressed approval of the system of grouping under which medical practitioners were to be approached by the Central Medical War Committee with a view to accepting medical commissions in the army. The purport of the memorandum was published in the same issue of THE LANCET, but the discussion at the Local Government Board centred round the grouping. The classification under which certain classes of medical practitioners were urged to join the army in preference to others was considerably criticised at the meeting, a fact which was clearly stated in the columns of THE LANCET. The classification was later modified.

SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE.

A meeting of the General Committee was held in the Royal College of Physicians of Edinburgh on Jan. 15th, Dr. Norman Walker (Convener) being in the chair. There were present Dr. A. H. F. Barbour, President of the Royal College of Physicians; Mr. James Hodsdon, President of the Royal College of Surgeons; Dr. Ebenezer Duncan, President of the Royal Faculty of Physicians and Surgeons of Glasgow; Professor J. A. Kynoch, Dean of the Faculty of Medicine, University of St. Andrews; Professor T. H. Bryce, Dean of the Faculty of Medicine of the University of Glasgow; Professor Harvey Littlejohn, Dean of the Faculty of Medicine, Edinburgh University; Dr. John C. McVail, Deputy Chairman, National Health Insurance Commission, Scotland; Professor R. Muir, University of Glasgow; Professor T. K. Monro, University of Glasgow; Dr. J. R. Hamilton, Chairman, Scottish Committee, British Medical Association; Dr. John Adams, Vice-Chairman, Scottish Committee, British Medical Association; Dr. John Playfair, President of the Edinburgh Medical Guild; Dr. John Stevens, secretary, Edinburgh Branch, British Medical Association; Dr. J. R. Currie, medical officer, National Health Insurance Commission, Scotland; Mr. T. H. Graham, secretary. Sir Donald MacAlister, K.C.B., President of the General Medical Council, and Dr. Alfred Cox, medical secretary, British Medical Association, were also present.

The Convener, in reporting upon the progress of the Medical Recruiting Scheme for 1916, stated that about 25 per cent. of the registered practitioners in Scotland had not yet made a return as requested in the Committee's memorandum which was circulated in December last, and he pointed out that in order to be fully prepared to meet any further demands which the War Office may make upon the profession it was essential that the Committee should possess a complete conspectus of the whole position of medical service in Scotland This was the object of the registration scheme, and it was most desirable that those practitioners who had not yet answered the inquiry should do so without further delay

The Presidents of the Royal College of Physicians, the Royal College of Surgeons, and the Royal Faculty of Physicians and Surgeons of Glasgow, and the Deans of the Faculties of Medicine in the Universities of St Andrews, Glasgow, Aberdeen, and Edinburgh, were appointed, with the Convener, to deal with all applications for letters of excuse, and to report to the Committee

---

THE WORK OF AN AIDE MAJOR

A correspondent who has been privileged to help in ambulance work in the forest of Argonne, the scene of so much fierce and prolonged fighting, sends us the accompanying photograph illustrating the routine morning's work of an *aide major* (assistant surgeon) of the French Army Medical Service, conducted, weather permitting, in the open air His duty is to interview and examine ailing combatants and to apply such treatment as his limited facilities allow Dry cupping has always been a popular and highly appreciated therapeutical measure among French practitioners, and the *infirmier*, or male nurse, is usually an expert "ventousier" (*ventouse* is the French for cupping glass, whence *ventousier*) It is the panacea for every "tendency to congestion," every pain or ache, and, in general, as a first aid treatment The cupping glass and direct auscultation (for the stethoscope is practically unknown in its country of origin) are the means of restoring peace of mind to many a troubled bosom in the trenches

Open air work of an *aide major* in the Argonne

BRIGHTON TERRITORIAL HOSPITAL.—Mr L. A Parry, M D, F R C S, sends the following notes of cases under treatment at the Brighton Territorial Hospital presenting points of special interest in connexion with gunshot and other wounds The notes have been grouped under regional headings

I *Head and neck —Fracture of the base of the skull with paralysis of cranial nerves* —In this patient there was a small punctured bullet wound just below the middle of the left orbit, with complete paralysis of the seventh and eighth nerves on the same side Subconjunctival hæmorrhage had taken place and some bleeding from the left ear An X ray picture was negative Either the bullet had not entered, the wound being merely a glancing one, or the radiogram failed to show it A fracture of the base of the skull was undoubtedly present, the petrous portion of the temporal bone being injured, thus accounting for the nerve paralysis ——*A case illustrating the advantage of the immediate excision of bullet wounds* —A patient was struck by shrapnel which tore open his scalp The wound was as soon as possible completely excised and sewn up It healed by first intention with a simple linear scar, with the saving of much time and the avoidance of the risk of septic complications ——*A case of gunshot wound of the mouth* —The patient was struck by a bullet at one angle of the mouth which was cut open The bullet passed right through the mouth, cutting the tongue, knocking out nearly all the teeth and portions of the alveoli, and passing out at the opposite angle of the mouth There was left a septic wound of the lips and cheeks which is healing with simple mouth washes A good deal of deformity will be left requiring a plastic operation later ——*A case of wound of the throat by shrapnel* —This man was struck by a bullet which made a deep gutter wound round the front of the throat from about the angle of one jaw to the same point on the other jaw He had a little hoarseness immediately after the injury but the larynx was not appreciably affected. The wound presented the same appearance as obtains in a case of cut throat

II *Trunk —Some examples of wounds of the chest* —A young soldier was shot through the lung by a rifle bullet, which entered behind the right shoulder and left at the level of the angle of the left scapula Severe hæmoptysis occurred, lasting two weeks There were also cough and dyspnœa A needle was inserted into the right chest and from it came what the patient thinks was clear fluid. A diagnosis of pneumothorax was made In one month from the receipt of the wound the patient was quite well, all the untoward symptoms having disappeared In another case the man was shot through the lower part of the chest by a bullet from a machine gun, which entered at the level of the eighth rib in the anterior axillary line and left the body on the opposite side at the same level but rather farther back. In its course the bullet must have traversed the right pleural cavity the liver, the stomach probably the spleen, and the left pleural cavity About half an hour after receiving the injury the patient drank some water and almost at once vomited a quantity of blood There was a doubt whether he had some slight spitting of blood Signs of a pneumothorax were present One month after being shot the patient was quite well all abnormal physical signs having disappeared

III *Extremities —Some cases of bullets lodged in bone* —A man had a whole shrapnel ball embedded in the head of the tibia A sinus led down to the bone and as this showed no sign of healing and the patient had a good deal of pain an exploratory operation was undertaken and the bullet removed. In the second case a bullet lodged in the lower end of the femur, and was easily removed through the entry wound. If no symptoms are caused by a bullet fixed in bone nothing need be done but if a sinus persists, or there is pain and disability, an operation should be carried out for its removal.——*Comminuted fractures*—The patient was shot in the wrist by a bullet, causing a compound fracture of radius and ulna. The wound was explored and a large number of small pieces of bone and cloth taken away After this it healed well, with satisfactory union of the bones in good position Unless comminuted fractures of the bones due to bullet wounds are early and thoroughly explored and all foreign bodies such as pieces of cloth, removed together with all loose fragments of bone, sinuses may persist for many years, causing much trouble and giving rise to many long and difficult operations for the removal of sequestra. Expectant treatment in this class of case is bad surgery Every comminuted fracture due to a bullet wound should be thoroughly explored at as early a date as possible The following is another example of this frequent class of case *Severe compound fracture of the tibia and fibula*—This man was wounded in the leg at about 100 yards range Both of the bones of the leg were much comminuted. The essentials of treatment were carried out—namely, exploration and removal of all loose pieces, free drainage, and immobilisation of the bones Too much attention has not been paid to the position of the fragments as this is, at this stage, a matter of secondary importance ——*Explosive wounds*—The first case is that of a man shot by a bullet which entered by a small circular aperture at the centre of the palm and came out at the back of the hand, making a large triangular explosive wound about 2 inches long on each side The man naturally attributed his injury to an explosive bullet The true explanation of this, as of nearly all so-called explosive wounds, is that enunciated in Teevan's law, which states that the entry wound is caused by the bullet alone the exit wound by the bullet, together with pieces of broken bone In the second case a bullet had passed right through the thigh, the entry wound at the back being a mere puncture, the exit wound in the front showing all the characteristics of an explosive wound, being large and gaping, with shreds of lacerated muscle. An X ray examination showed no fracture of the bone, though from the appearance of the wound a fracture would have certainly been expected. This case is an interesting example of a rather rare event—namely an explosive wound without any fracture of bone. The bullet must have turned in its course through the thigh, being probably deflected by the bone without causing any bony injury, and was then forced sideways through the skin thus giving the explosive appearance.——*Traumatic aneurysm of the common femoral artery*—A rifle bullet passed right through this patient's leg, the wound of entry being in the lower part of the left buttock, behind, that of the exit in the front of the thigh just internal to the common femoral artery and about 2 inches below Poupart's ligament both wounds being quite small punctures and having healed without sepsis He was admitted four days after being struck when there was an oval swelling about 1¾ in by 1¼ in over the common femoral artery, which pulsated and over which a thrill could be felt There was no interference with the peripheral circulation the pulse at the ankle being similar to that on the other side and having a rate of between 80 and 90 per minute A definite murmur was transmitted upwards and downwards. The sac was over the femoral artery and no secondary results of pressure or deficient blood supply were apparent An ice-bag was applied and rest in bed ordered The thrill persisted only for about 10 days One month later the sac was slightly diminished in size the thrill had disappeared and the patient was suffering no discomfort ——*[illegible] severe injury to the forearm*—This patient presented a large irregular wound on the front of the lower part of the forearm with a similar wound at the back daylight showing between the two Pieces of bone and fragments of the soft parts had been blown right out The tendons of the various muscles of the forearm were exposed but the main vessels and nerves were intact as shown by the fact that the circulation below was satisfactory and sensation normal An X ray photograph showed comminution of [illegible] the gap between the end An attempt is being made to save the arm although it is extremely doubtful whether this will be possible Even if saved the limb will probably be of very little use ——*Compound comminuted fracture of the patella*—This man was struck by a fragment of trench bomb which caused a comminuted fracture of the knee-cap There was a non purulent effusion into the joint cavity Wounds from this variety of missile are now common, but they present no special features They cause practically the same injuries as are inflicted by any piece of shell.——*Large superficial flesh wound*—This man had in the middle of the back of his thigh a large oval wound, irregular and jagged. He said he had been struck by an explosive bullet As this was the only wound, probably a piece of shell was the actual cause of his injury Saline solution was used as a dressing, and this proved, as in a large number of other cases in which it was employed, very satisfactory, the wound granulating up in a perfectly healthy manner ——*Phlebitis from a blow by a piece of spent shell*—The patient was struck in the middle of the calf by a large piece of a nearly spent shell He had not previously had any trouble with his veins A simple inflammation of the veins was the result, which took many weeks to subside

VACANCIES FOR MEDICAL OFFICERS—There remain several vacancies in the commissioned ranks of the 2nd London Sanitary Company for foreign service Candidates holding a public health diploma will be given a preference, and on being accepted will proceed on service after a short period for training Applications should be addressed to Captain Caley, officer commanding 2nd London Sanitary Company, Duke of York's Headquarters, Chelsea, S W

CONVALESCENT HOMES—General Seely, formerly Secretary of State for War, has placed Brooke Hill, Isle of Wight at the disposal of the Royal Flying Corps for use as an officers' convalescent home—In order to provide a home for soldiers and sailors who are more or less permanently incapacitated for ordinary work Mr William Cresswell Gray, of West Hartlepool, has offered to make a gift of Membland Hall, Revelstoke, South Devon, to the nation.—The buildings at Prior Park, Bath, are being fitted up as a convalescent home for men of the Canadian Expeditionary Force—The annexe to the Star and Garter Hospital at Richmond has been completed, and on Jan 15th a number of convalescent soldiers and sailors were brought from London in motor ambulances The hotel itself is in course of reconstruction as a hospital for wounded men

THE DILKE MEMORIAL HOSPITAL—The sub-committee of the Dilke Memorial Hospital, which is to be erected near the Speech House, Forest of Dean has just issued a report The new institution is to provide accommodation for eight beds, exclusive of the resident staff. £3000 have been promised towards the necessary expenditure by an anonymous donor provided a similar amount is raised by the public. When this sum is obtained the Crown have offered £500 and £25 a year towards the maintenance, the cost of which is estimated at about £400 per annum

WOMEN'S MATERNITY UNIT FOR RUSSIA—A maternity unit organised by the National Union of Women's Suffrage Societies has been accepted by the Russian authorities and is expected to leave shortly for Petrograd where it will be known as the British Women's Hospital. Sixteen beds are to be provided The staff will consist of two women medical officers, one with clinical and one with sanitary duties a general organiser a matron and six nurses The medical officer is Miss M E Mar M B Ch B lately returned from Serbia Russia is doing what it can to provide maternity help for the constantly increasing stream of refugees but Russian medical women as well as men have been mobilised and are not available for civilian practice The cost of the unit for six months is estimated at £5000 Generous donations in money and clothes have been already received from the Union of Trained Nurses and medical instruments and supplies of any kind will be welcome. Milk foods are specially wanted The honorary treasurer's address is 14 Great Smith Street S W

OBITUARY OF THE WAR

ERNEST OCTAVIUS WIGHT, L R C P EDIN, M R C S ENG, D P H,

COLONEL AND ASSISTANT DIRECTOR, ARMY MEDICAL SERVICE

Colonel E O Wight who was killed in action in Flanders on Dec 19th last at the age of 57 years, was the youngest son of the late Dr Robert Wight F R S, of Shinfield near Reading He was educated at Wellington College, and then entered at St Mary's Hospital, where he was a prizeman and, as a contemporary writes, "well known for his determination to gain his object, both at his work and in sports " After obtaining his double qualification in 1881, he entered the Army Medical Service, reaching the rank of lieutenant-colonel in 1902, and retiring in 1907 On the formation of the Territorial Force he accepted the post of Deputy Assistant Director of Medical Services, Home Counties Division, in which capacity he was employed when war broke out In April last he was offered the post of Assistant Director of Medical Services, 49th Division, which had been ordered abroad, and he was serving in this capacity at the time of his death He was killed by a shell whilst assisting to extricate some of his motor ambulances from a dangerous position He saw active service in the Lushai Expedition of 1892 and held the Royal Humane Society's bronze medal and two vellum testimonials for saving lives from drowning on three different occasions One of his senior officers, in writing of him says "He was a man who had become proverbial as one who had no fear, he was an object of devotion and reverence to his own officers and men, ever setting them a fine example of duty All mourn him, as they have lost not only a true friend, but also a wise director and an original and clever organiser of things for their good, one whose whole heart and soul was in his work " Of his personal attributes a medical friend says "His kindly disposition and cheery laugh made him a great favourite with every one." Colonel Wight married, in 18[illegible] Janet Leslie, youngest daughter of the late Peter Denny LL D, of Helenslee, Dumbarton He leaves a widow and three children two daughters and a son, who is a cadet at Dartmouth College

WILLIAM FRANK THOMPSON, B A. CANTAB, M R C S L R C P LOND,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS

Lieutenant W F Thompson, who died in France as the result of wounds received on Dec 28th, the son of Mr W W Thompson, of Brondesbury, was educated at the Leys School, Cambridge, where he was one of a small group of boys whose strength of character and skill at games made them the Olympians of their time Of that group he is the third to lay down his life for his country in the war From the Leys School he went to King's College, Cambridge, where he graduated in 1909 and represented the University at lacrosse From Cambridge he proceeded to St Bartholomew's Hospital, where he qualified in 1912, and where during the earlier part of the war he held one of those condensed and exceedingly hard worked house appointments which the war made necessary Joining the Royal Army Medical Corps as honorary lieutenant in July 1915, and gazetted to the rank of full lieutenant on Oct 9th, he was posted to the 99th Field Ambulance, and after a period of training went with it to France, where he was mortally wounded by the bursting of a shell near his ambulance and died in hospital on New Year's Day, 1916, at the age of 28 Tall, strong, friendly and efficient, he was marked to succeed in any branch of work he took up In entering his name on the Roll of Honour we commemorate a loss which will be very deeply felt by his friends inside and outside the medical profession

Medical News

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND —At the Second Professional Examination in Anatomy and Physiology held on Jan. 6th, 7th, 10th, and 11th, 96 candidates presented themselves of whom 67 were approved and 29 were rejected The following are the names and medical schools of the successful candidates —

Ralph William Codrington Ball Middlesex Hospital George Arthur Emmanuel Barnes, University College, Anthony Blackstock King's College Eric John Swithin Bonnett St Thomas's Hospital Martin Vincent Boucaud St Bartholomew's Hospital Charles Reginald Cade Guy's Hospital; John Douglas Magor Cardell, St Thomas's Hospital Thomas Carlyle St Bartholomew's Hospital Nai Cheua Middlesex Hospital Wilfred Bayley Christopherson St. Bartholomew's Hospital William Arnold Clements Birmingham University Charles Eric Cobb St Thomas's Hospital Alfred Innes Cox Middlesex Hospital Hedley Chave Cox St Bartholomew's Hospital Carl Knight Cullen, London Hospital Thomas Davies, B Sc. Cantab Cambridge and Bristol Universities

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A quarterly meeting of the Council was held on Jan 13th, Sir W Watson Cheyne, the President being in the chair In accordance with the recommendation of the Library Committee it was resolved that the library shall be closed at 6 30 instead of at 7 o clock. It was resolved to contribute the sum of 50 guineas to the joint fund of the British Red Cross Society and the Order of St John of Jerusalem Mr H J Waring was re elected a member of the Court of Examiners It was decided to remove from the roll of Members a Member whose name had been previously removed from the Medical Register The President reported the delivery by Sir Anthony Bowlby, on Dec. 20th last, of the Bradshaw lecture on "Wounds in War" The best thanks of the Council were given to Sir Anthony Bowlby for his lecture and he was requested to publish it The President reported that Sir G H Makins had consented to deliver the next Hunterian oration, and accordingly declared him to be appointed Hunterian Orator for 1917 The President reported that he had granted the use of the lecture theatre in December last (1) to the University of London for five lectures on Recent Work on Alimentary Toxæmias, by Dr E Mellanby, acting superintendent of the Brown Animal Sanitary Institution, and (2) to Major T B Layton, R A M C, for three demonstrations to men of the 2/4 London Field Ambulance Licences to practise dentistry were conferred upon the following three candidates —

Bertrand Kemp Jackson Liverpool University and George Evan Henry Holt Phillips and John Morley Stebbings Guy's Hospital

ROYAL METEOROLOGICAL SOCIETY.—The annual general meeting of this society was held on Jan 19th at the Surveyors Institution, Great George-street, Westminster, Major H G Lyons F R S the President, being in the chair The report of the council for 1915 was laid before the Fellows and the Symons memorial gold medal, which is awarded biennially for distinguished work in connexion with meteorological science was presented for transmission to Dr C A Angot Bureau Central Météorologique de France The President delivered an address on the Winter Climate of the Eastern Mediterranean of considerable topical interest

MEMORIAL SERVICE AT ST BARTHOLOMEW'S.—A memorial service was held on Jan 13th in the chapel of St Bartholomew the Less within the precincts of the hospital for the 21 past or present students who have lost their lives during the last year of fighting The service was largely attended by the governors members of the staff and students as well as by the immediate relatives and friends of the deceased

Parliamentary Intelligence

HOUSE OF COMMONS

WEDNESDAY, JAN 12TH

Medical Men and War Service

Mr SHIRLEY BENN asked the Under Secretary for War by whose authority the Central Medical War Committee which was now occupied in recruiting doctors to the Royal Army Medical Corps was chosen by whom were its powers defined and by whose nominations had its members been selected Mr TENNANT wrote in reply The Committee referred to in the question was I am informed appointed and its terms of reference settled by the British Medical Association at its annual Representative Meeting in July [illegible] medical [illegible] War Office [illegible] Army [illegible] his qualifications to the best possible use to deal with all matters affecting the medical profession arising in connexion with the war and to report to the Council (of the British Medical Association)" After a conference at the War Office with the Director General of the Army Medical Service the Committee was informed on August 9th, 1915 (in a letter which has been published), that the Director General hoped to receive from the Committee much help in his work of providing officers for the Royal Army Medical Corps, and was glad to recognise the Committee as a medium for dealing with the great problem which faced the medical profession—namely, how to supply medical officers for the forces and at the same time to protect the needs of the civil population, and the Committee was accordingly authorised to make appeals to the profession with the object of securing those needs A further conference took place at the War Office with the Director General of Recruiting on Nov 5th last on the same subject and to the same effect As a result of these conferences this Committee, which has Local Committees in all parts of the country, has been endeavouring to procure and to coördinate offers from members of the medical profession of service in the Royal Army Medical Corps Applications for such commissions are decided upon by the War Office, after they have been referred to this Committee for consideration in relation to the medical needs of the civil population in the areas concerned in each case, and after consultation with the Insurance Commission and where necessary with the Local Government Board and the Board of Education Analogous arrangements exist in regard to Scotland I should add that the War Office has received and is receiving very valuable assistance from these Committees

Mr SHIRLEY BENN further asked the right honourable gentleman why the medical profession was not starred, since a medical man represented a skilled worker who was not easily replaced, and whose training occasioned considerable outlay and occupied a long period of time—Mr TENNANT (in a written answer) replied Special arrangements have been made with regard to the recruitment of the medical profession, with a view of ensuring all adequate attendance on the troops without unnecessarily dislocating the medical needs of the civil population The question of starring does not arise

Mr SHIRLEY BENN asked the right honourable gentleman whether the Government had sanctioned the recruiting, through the agency of the Central Medical War Committee, of medical men up to the age of 45 the limit of age for the rest of the nation being 41—Mr TENNANT wrote in reply The age limit referred to in the question relates to medical men applying for commissions in the R A.M C, and not to recruits for the combatant services in which the age limit of 41 applies

Recruitment of Medical Students

Mr SHIRLEY BENN asked the Under Secretary for War whether he was aware of the risk of cutting off at its source the supply of medical aid both for the army and for the civil population, which was incurred by recruiting first- and second year medical students and would he see that the practice was discontinued—Mr TENNANT wrote in reply The present policy was undertaken after the most careful consideration, but the statistics bearing upon the matter are being considered

Discharge for Physical Incapacity from the Army

Mr RICHARD LAMBERT asked the Under Secretary for War whether all men who were in future passed into the army as medically fit would be entitled to pensions if discharged for physical incapacity of any kind.—Mr TENNANT replied No, Sir, I am not prepared in this matter to go further than I went in the answer which I gave on Nov 10th to the honourable Member for East Edinburgh

Mr HOGGE Has the right honourable gentleman sufficiently realised the importance of this point? Seeing that these men are accepted by the medical authorities as medically fit will the War Office claim, in the event of physical breakdown that they contracted the disease before they were admitted to the army?—Mr TENNANT I think that I gave my honourable friend a full reply on this matter the other day It is not possible for the military department to take responsibility in the case of men who have not contracted illness in the service of the State I am sure that in the interests of the State my honourable friend does not wish us to do anything of the kind

Mr HOGGE How does my right honourable friend meet the point that these men are accepted as medically fit —Mr TENNANT The disease may not have been detected, there may have been some previous illness

Mr [illegible] There is a class of men who have some [illegible] which would not have emerged had it not been for the hardships of military service The disease [illegible] owing to these hardships and [illegible] consideration [illegible] is the general position [illegible] War Office in regard to such cases —Mr TENNANT I [illegible] large a question across the floor of the House But I will say that, speaking generally, that is a medical matter and the medical authorities would state whether they considered that the actual service of the State had been the reason for the breakdown of the man If it had been the man would, of course, receive the pension to which he was entitled

Military Service and the Medically Unfit

Mr **ALDEN** asked the Under Secretary for War whether single men who previous to the Derby scheme had offered themselves for enlistment and were rejected as medically unfit, and who under the circumstances, thought it unnecessary to attest under the Derby scheme, were included in the Military Service Bill, and whether he would see to it that they were not conscripted and compelled to attest —Mr **TENNANT** answered As the Bill stands these men are not excluded, but if their physical disability still renders them unfitted for any form of military service they cannot be held to serve

THURSDAY, JAN 13TH

An Officer of the Australian Medical Corps

Captain **AMERY** asked the Under Secretary for War whether Lieutenant-Colonel J W Barrett, Australian Medical Corps, occupied the imperial appointments of Assistant Director of Medical Services on the staff of the Director of Medical Services, Egypt, and consulting oculist to His Majesty's forces in Egypt, whether he was removed from these offices without inquiry by the Australian Government on a recommendation of the Army Council, which the general officer commanding in Egypt subsequently pointed out was due to a misunderstanding, whether a court of inquiry had been held and what was the finding of that court, and whether, if that report was favourable, the Army Council was prepared to reinstate Lieutenant-Colonel Barrett, or whether he was prepared to make any statement with regard to the value of the work done by Lieutenant-Colonel Barrett —Mr **TENNANT** replied I believe the facts as stated in the first two parts of the question are substantially correct A court of inquiry was held in Egypt in October last year, and in its finding the court exonerated Lieutenant-Colonel Barrett and spoke in the highest terms of his work The High Commissioner of the Commonwealth was informed that there was no objection to Lieutenant-Colonel Barrett being employed in Egypt or elsewhere provided that the Government of the Commonwealth concurred

Soldiers and Surgical Boots

Colonel **WHITE** asked the Under Secretary for War whether he was aware that there was a considerable number of young soldiers who were either unfitted for drafts or had to be discharged from the service owing to their suffering from hammer toes or similar disability, and whether he would consider the advisability, in the less aggravated cases, of having these men fitted with surgical boots which might render them fit for service in any event with a non combatant unit —Mr **TENNANT** wrote in reply In the opinion of my medical advisers the issue of surgical boots to the men mentioned is not likely to render them fit for service, and even if such boots were issued it would be quite impossible to replace them if they were lost or worn out on service

Vaccination Statistics

Mr **PATRICK WHITE** asked the Parliamentary Secretary to the Local Government Board whether he could state the number of children vaccinated in Great Britain in the years 1913, 1914 and 1915, respectively, and the number exempted on account of conscientious objections on the part of their parents, and whether any and if so, how many prosecutions were instituted against parents for non compliance with the law during each of the years mentioned —Mr **HAYES FISHER** answered The number of successful vaccinations for which vaccination officers received certificates at all ages in England and Wales was in 1913, 430,470, and in 1914, 404,616, and the number of declarations of conscientious objection to vaccination in 1913 308,235, and in 1914, 321,313 I cannot give the actual number of children vaccinated nor the figures for 1915, which are not yet available As to the figures for Scotland a question should be addressed to the Secretary for Scotland It appears from the criminal statistics for the year 1913 that 146 persons were proceeded against in that year for offences against the Vaccination Acts The statistics for 1914 and 1915 have not yet been published

TUESDAY, JAN 18TH

The Eyesight of Recruits

Sir **JOHN ROLLESTON** asked the Under Secretary for War whether the War Office was aware that only a medical eye specialist was capable of deciding whether a would be recruit with defective vision was or was not suitable for military service seeing that the sight tests did not discriminate between disease and errors of refraction corrigible by lenses and why the services of medical eye specialists were not made use of by the War Office —Mr **TENNANT** wrote in reply Medical eye specialists are made use of by the War Office in cases where their services are considered to be required

Sir **JOHN ROLLESTON** asked the right honourable gentleman whether it was the case that the War Office did not recognise the certificate of medical eye specialists with respect to the sight of would be recruits —Mr **TENNANT** replied The certificates of medical eye specialists are treated in exactly the same way as certificates from any other medical men They may aid the medical examiner of recruits, but they cannot absolve him from his responsibility in passing or rejecting the recruit In cases of doubtful vision the recruit will be referred for the opinion of an official medical eye specialist

Sir **JOHN ROLLESTON** also asked the right honourable gentleman whether he would consider the advisability of recruits who failed to respond freely to the sight tests being at once sent to a medical eye specialist to be examined as to their visual fitness for enlistment, and to obtain the needed prescription if glasses would bring the sight up to the required standard —Mr **TENNANT** answered Special ophthalmic surgeons are available in all commands to whom cases of doubt or difficulty will be referred

WEDNESDAY, JAN 19TH

Medical Students and Military Service

During the debate in Committee on the Military Service Bill

Mr J H **THOMAS** moved an amendment that a certificate of exemption might be granted to a man "on the ground that he is a medical student who can more advantageously complete his medical training in order to render national service as a medical practitioner

Mr **TENNANT** (Under Secretary for War said that it was proposed to continue the War Office policy that students in the fourth and fifth years should be left to continue their studies That was to say, those who had passed the examination in the third year would be free Those who failed to pass the examination in the third year would not be considered in that category The first- and second year students would be held for service in the forces of the Crown. The Government was carefully examining the whole position with regard to the possible shortage of medical men in the future It had for that purpose enlisted the services of Sir Donald MacAlister, President of the General Medical Council, who had undertaken a careful survey of the whole situation in the medical schools and was going to report to the Government on the subject

Mr **SNOWDEN** expressed regret that the Government was not prepared to take a longer view of the situation

The amendment was withdrawn

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions and others possessing information suitable for this column are invited to forward to THE LANCET *Office directed to the Sub Editor not later than 9 o clock on the Thursday morning of each week such information for gratuitous publication*

ANDERSON C B C (Final Year Student) has been appointed to the Surgical Out patient Department at the Edinburgh Royal Infirmary

BLAIR C. E M B Ch B Edin has been appointed Resident Physician at the Edinburgh Royal Infirmary

BURNET J M D Edin has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Edinburgh South District of the county of Edinburgh

CARRUTHERS G J R M B Ch B Edin has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Edinburgh, North District of the county of Edinburgh

Notes, Short Comments, and Answers to Correspondents

MEDICAL MEN AND THE ALLEGED SHORTAGE OF PETROL

THE importers and proprietors of a well known motor spirit have issued a circular in which they regret the inconvenience which may be caused to their clients by any temporary difficulties occurring in the delivery of their orders through the necessary attention to Government demands They go on to ask their clients to limit their requirements to a minimum, to use every possible economy in the quantities consumed, and to refrain from the retention of a stock larger than is absolutely necessary The medical profession is entirely in sympathy with any movement for economy in the use of petrol Anyone who has seen the pleasure traffic which still prevails on Sundays on certain of the big roads leading into and out of London must know that there is reckless use of a commodity which should be carefully saved for national purposes But it is equally evident that the petrol used by a medical man serves a direct national purpose and that he should have the preference over the mere pleasure-seeker or the man who uses his car simply to escape the discomforts of railway travelling All this is indeed so obvious that we should have hesitated to mention it, were it not that we have been assured that medical men have received these circulars without any accompanying statement that in case of an actual shortage of petrol a preference would be given to those requiring it for medical purposes

HOME MADE EAU DE COLOGNE

WE have received from the lady superintendent of the Nursing Home, Shear Bank road, Blackburn, a sample of eau-de Cologne made by herself from an old French prescription The prescription is evidently a good one, as the scent prepared brings to mind the classic fragrance of this article The product demonstrates that eau de Cologne can be produced at home which is in no way inferior to the familiar article The profit on sales is to be handed over to a fund in aid of sick or wounded sailors and soldiers

THE UNIVERSITY OF THE PHILIPPINES

BULLETIN No 5 of the University of the Philippines contains a history of the College of Medicine and Surgery which was established by the Government of the Philippine Islands in 1907 This institution is the first department of the future University of the Philippines and was opened for class work and instruction in 1910 Clinical instruction is given in the Philippine General Hospital, which has about 300 beds and also in the Free Dispensary Instruction in dangerous communicable diseases is given at the San Lazaro hospital for infectious diseases with its departments for incurable tuberculosis, small pox diphtheria plague cholera, and other diseases There are also available for teaching purposes the San Juan del Monte Tuberculosis Sanatorium, the institution for the feeding and care of abnormal and undeveloped children and the tuberculosis free dispensaries of the city of Manila In all these institutions there is an abundance of clinical material Students who are not candidates for degrees granted by the College of Medicine and Surgery may be admitted to the various courses Full particulars may be obtained from the Dean, College of Medicine and Surgery, Manila

OPEN AIR TREATMENT IN A SLUM

REPORTING on the condition of the Brady street area the public health committee of the Bethnal Green borough council says We understand that for a time some families were in occupation of rooms the rear walls of which had been removed, such families being thus exposed to the inclemency of the weather

M O H has complained to the water engineer that sheep droppings frequently get into the reservoir which supplies the town with drinking water, and has been met with the remark "We don't mind about sheep" The reply indicates that the water authority is too phlegmatic The pollution of water supplies with manurial matters of any kind is most objectionable All responsible water authorities hold that the land nearest to reservoirs should not be manured, and sheep and cattle should be prevented from gaining access

J S, Captain, R A M C—The following can be safely recommended *Physiology*—"Principles of Human Physiology By E H Starling, M D, F R S Second edition 21*s* net (London J and A. Churchill) For revision "Essentials of Physiology" By F A Bainbridge, M D, D Sc, and J A Menzies, M D 1914 Price 10*s* 6*d* net (London Longmans, Green and Co) 'Cole's Physiological Chemistry (Cambridge W Heffer and Sons) *Anatomy*—"Cunningham's Manual of Practical Anatomy' Revised and edited by Arthur Robinson In two parts 1914 (London Henry Frowde and Hodder and Stoughton) Human Embryology and Morphology By Arthur Keith, M D, F R S (London Baillière, Tindall, and Cox), or 'A Manual of Human Embryology, by J Playfair McMurrich (London Baillière, Tindall, and Cox) "Landmarks and Surface Markings of the Human Body" By L B Rawling, B C, F.R C S Price 5*s* net (London H K. Lewis and Co, Limited)

R L—We are in agreement with the points our correspondent desires to make, but it seems to have escaped his attention that 143 schools, colleges, and institutes are already recognised as teaching institutions for the ancillary sciences by the licensing bodies and approved by the General Medical Council A list of these is included in the "Regulations of the Council in regard to the Registration of Medical and Dental Students," published by Constable and Co, London The last issue is dated June, 1915

H W, M B, B S, may safely consult one or more of the following books "Introduction to Study of Hypnotism," Dr H. E Wingfield 5*s* net (Baillière, Tindall, and Cox, London) 'Hypnotism and Treatment by Suggestion," Dr J Milne Bramwell 5*s* net (Cassell and Co, London) Hypnotism and Suggestion, Dr Lloyd Tuckey 10*s* 6*d* net (Baillière, Tindall, and Cox, London)

A V F—Some of the suggestions have already been put into practice In an account of the work of field ambulances published in the *British Medical Journal* some weeks ago, bathing establishments behind the lines were described at which washing of clothes and disinfection were carried out on a large scale, dealing with an average of nearly 1000 men a day for many successive weeks

A F H—Before the war we understand that the exact opposite prevailed, and advancement was more rapid and certain in our correspondent's service, where a lieutenant colonelcy could be counted on after 20 years instead of an indefinite wait for a vacancy

R G—Certainly not The procedure is perfectly well known to every practitioner and it is necessary to take the opinion of the medical adviser to whom the patient is already well known

COMMUNICATIONS not noticed in our present issue will receive attention in our next

MEETINGS OF SECTIONS

Monday Jan. 24th.

ODONTOLOGY (*Hon Secretaries—F R. Smyth F N Doubleday J Howard Mummery*): at 8 P M

Paper

Mr W Courtney Lyne (communicated by Mr Montagu F Hopson) *The Significance of the Radiographs of the Piltdown Teeth* Professor Arthur Keith Professor A. S Underwood and Dr Smith Woodward will take part in the discussion.

Casual Communication

Mr Rushton: Total Absence from Deciduous and Permanent Dentition

Tuesday, Jan. 25th

PSYCHIATRY (Hon. Secretaries—Bernard Hart, G F Barham): at 8.30 P.M

War Discussion

A Special Discussion on the "Functional Neuroses caused by Shell Shock without Visible Signs of Injury" will be opened by Dr Mott F R.S and will be adjourned to the Meeting of Neurology on Thursday Jan 27th (see notice below)

N B —Members of other Sections interested in the subject are specially invited to be present

Thursday, Jan. 27th.

NEUROLOGY (Hon Secretaries—H Campbell Thomson *C M Hinds Howell*): at 8 30 P.M

The Special Discussion on the Functional Neuroses caused by Shell Shock without Visible Signs of Injury" (see above Section of Psychiatry) will be continued

The chair will be taken by the President (Dr James Taylor) and Dr Batten Dr Farquhar Buzzard Dr J S Collier Dr E G Fearnsides Dr Wilfred Harris and Dr Campbell Thomson will speak

Members wishing to take part in the discussion should communicate at once with Dr Hinds Howell 145 Harley street W

Friday Jan 28th.

STUDY OF DISEASE IN CHILDREN (Hon Secretaries—J D Rolleston A. S Blundell Bankart, Sidney Gifford): at 4.30 P M

Cases

Mr *Sydney Stephenson: Dyspituitarism in a Girl of 15 Years*

Dr J D Rolleston: Transient Hemiplegia in *Diphtheria* with *Lesions of the Finger-nails*

Dr J L. Bunch: *Papillomatous Growth in a Scar*

Dr Eric Pritchard (?) Cerebral Tumour in a Child

Dr C O Hawthorne: *Double Optic Neuritis*

Specimens

Dr E C Williams: *Heart showing Infiltration by Large Round-celled Sarcoma.*

Miss M B Stogden and Miss J H Younger (Introduced by Dr Eric Pritchard): *Congenital Double Hydro-ureter*

Short Paper

Dr J Porter Parkinson: Nephritis without Albuminuria

MEDICO LEGAL SOCIETY 11 Chandos-street Cavendish-square W

TUESDAY —5 P M Exhibits. Short Communication —Sir John Collie: Short Account of a *Criminal Case* Was the Plea of *'Qualified Responsibility" Justifiable?*

HUNTERIAN SOCIETY *Guy's Hospital London Bridge S E*

WEDNESDAY —4 P M Clinical Afternoon Cases of Clinical Interest will be shown by, or for members of the staff of Guy's Hospital.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE West London Hospital Hammersmith road W

MONDAY —10 A.M. *Dr* Simson: *Diseases of Women.* 2 P.M., Medical and Surgical Clinics. X Rays Mr Gray: Operations Mr B Harman: Diseases of the Eye.

TUESDAY —2 P M, Medical and Surgical *Clinics* X Rays Mr Addison: *Operations.* Dr Banks Davis: *Diseases of the Throat, Nose, and Ear* Dr Pernet: Diseases of the Skin.

WEDNESDAY —10 A.M, Dr Saunders: *Diseases of Children* Dr Banks Davis: Operations *of the Throat,* Nose and Ear 2 P.M., Medical and Surgical Clinics X Rays. Mr Pardoe: Operations. Dr Simson: Diseases of Women.

THURSDAY —2 P.M., Medical and Surgical Clinics X Rays Mr Gray: *Operations* Mr B Harman: Diseases of the Eye

FRIDAY —10 A.M., Dr Simson Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr Addison: Operations. Dr Banks Davis: Diseases of the Throat, Nose, and Ear Dr Pernet: Diseases of the Skin.

SATURDAY —10 A.M. Dr Saunders: Diseases of Children. Dr Banks Davis: Operations of the Throat, Nose, and Ear Mr B Harman: Eye Operations 2 P.M. Medical and Surgical Clinics X Rays. Mr Pardoe: Operations.

RTH EAST LONDON POST-GRADUATE COLLEGE Prince of Wales's General Hospital, Tottenham, N

MONDAY —Clinics:—10.30 A.M. Surgical Out patients (Mr E Gillespie) 2.30 P.M. Medical Out patients (Dr T R. Whipham): Gynæcological Out patients (Dr Banister) 3 P.M., Medical In patients (Dr R M Leslie)

TUESDAY —2.30 P.M. Surgical Operations (Mr Carson) Clinics:—Medical Out patients (Dr A. G Auld) Surgical Out patients (Mr Howell Evans) Nose, Throat, and Ear Out-patients (Mr C H Hayton) Radiography (Dr Metcalfe) 3.30 P.M., Medical In patients (Dr A. J Whiting)

WEDNESDAY —Clinics:—2.30 P.M Throat Operations (Mr C H. Hayton) Children Out patients (Dr T R. Whipham) Eye Out-patients (Mr R. P Brooks) Skin Out-patients (Dr H W Barber) 5.30 P.M Eye Operations (Mr R. P Brooks)

THURSDAY —2.30 P.M., Gynæcological Operations (Dr A. E Giles) Clinics —Medical Out patients (Dr A. J Whiting) Surgical Out patients (Mr Carson) Radiography (Dr Metcalfe) 3 P.M., Medical In patients (Dr R. M. Leslie)

FRIDAY —2.30 P.M. Surgical Operations (Mr Howell Evans) Clinics:—Medical Out patients (Dr A. G Auld) Surgical Out-patients (Mr E Gillespie) Eye Out patients (Mr R. P Brooks)

HE THROAT HOSPITAL, Golden square W

MONDAY —5.15 P.M Special Demonstration of Selected Cases

THURSDAY —5 15 P M Clinical Lecture.

T JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49 Leicester-square W C

TUESDAY —4 P M Dr J L. Bunch: Some Common Skin Diseases

THURSDAY —6 P.M. Chesterfield Lecture —Dr M. Dockrell: The Diagnosis and Treatment of the late Eruptions of Syphilis

ROYAL INSTITUTION OF GREAT BRITAIN Albemarle-street Piccadilly W

TUESDAY —3 P M., Prof C S Sherrington The Physiology of Anger and Fear (Lecture II)

FRIDAY —5 30 P M Dr L. Hill: The Science of Clothing and the Prevention of Trench Feet

For further particulars of the above Lectures &c , see Advertisement Pages

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed ' To the Sub Editor '

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed ' To the Manager*

We cannot undertake to return MSS not used

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index and Title page to Vol. II of 1915 were given in THE LANCET of Dec 25th 1915

VOLUMES AND CASES

VOLUMES for the second half of the year 1915 are now ready Bound in cloth gilt lettered price 16s carriage extra.

Cases for binding the half-year's numbers are now ready Cloth [illegible] price 2s by post 2s 4d

[illegible] accompanied by [illegible]

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

ALTERATION OF INLAND SUBSCRIPTION RATES

OWING to the alteration in the Inland Newspaper Postal rate, the postage on each copy of THE LANCET will in future be 1*d* , and sometimes 1½*d*

The revised Inland Subscription rates are —

One Year	£1	3	3
Six Months	0	13	8
Three Months	0	7	0

The rates for the Colonies and Abroad (thin paper edition) will be as usual —

One Year	£1	5	0
Six Months	0	14	0
Three Months	0	7	0

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

ADVERTISEMENT RATES

The Lettsomian Lectures

ON

THE EFFECTS OF HIGH EXPLOSIVES UPON THE CENTRAL NERVOUS SYSTEM

Delivered before the Medical Society of London

By FRED W MOTT, M D Lond, F R C P Lond, Hon LL D Edin, F R S,
MAJOR R A M C (T) 4th London General Hospital Pathologist to the London County Council Asylums

LECTURE I

(Delivered on Feb 7th)

Mr. President and Gentlemen,—Permit me to thank you for the great honour the Medical Society of London has done me in asking me to give the Lettsomian lectures this year The society has been fortunate in having had addresses and discussions on most of the medical and surgical problems concerning the war, with the exception of the effects of high explosives upon the central nervous system in the production of functional neuroses and psychoses As I have had the opportunity of studying these effects I ventured to change the subject which I at first contemplated

The employment of high explosives combined with trench warfare has produced a new epoch in military medical science This war was recently described at a Labour Congress as a barbarous, unromantic machine war Yet in no war of the past has individual courage and self sacrifice shone with greater lustre, for the contemptible little army in the retreat from Mons fought against overwhelming odds and covered itself with glory Again, in the terribly anxious times when the enemy tried to break through to Calais, what could have surpassed the courage and self sacrifice of our men in the trenches on the Yser, or the gallant stand of the Canadians when the Germans sprang the gas upon us? Lastly, the landing of the Anzacs is one of the finest and most romantic deeds in the history of war

High explosives contained in huge shells have played a prominent part in this war, and apart from the effects produced by direct material injury to the central nervous system, there is the *moral* effect of the continued anxious tension of what may happen, which combined with the terror caused by the horrible sights of death and destruction around tends to exhaust and eventually even shatter the strongest nervous system To live in trenches or underground for days or weeks, exposed continually to wet, cold, and often owing to the shelling of the communication trenches to hunger combined with fearful tension and apprehension, may so lower the vital resistance of the strongest nervous system that a shell bursting near, and without causing any visible injury, is sufficient to lead to a sudden loss of consciousness So that in considering the effects of high explosives it is absolutely necessary to take into account the state of the nervous system of the individual at the time of the "shock caused by the explosive A neuro potentially sound soldier in this trench warfare may from the stress of prolonged active service acquire a neurasthenic condition and it stands to reason that a soldier who has become neurasthenic from a head injury or from the acquirement of a disease prior to his enlistment will not stand the strain as well as a neuro potentially sound man Again if in a soldier there is an inborn timorous or neurotic disposition or an inborn germinal or acquired neuropathic or psychopathic taint causing a *locus minoris resistentiæ* in the central nervous system, it necessarily follows that he will be less able to withstand the terrifying effects of shell fire and the stress of trench warfare Thus, whether a tendency to a neurasthenic condition has been acquired or is more or less inborn, an emotional experience such as fright is more liable to develop the symptoms of a functional neurosis or psychosis

The Effects of High Explosives upon the Central Nervous System

The effects of high explosives upon the central nervous system fall into three groups 1 Immediately fatal either from pieces of shell, stones, rocks, or portions of buildings striking the individual, causing instant death, or the person may be buried from the explosion of a mine Again, instant death must have occurred in groups of men from the effects of shell fire and yet no visible injury has been found to account for it This matter I shall discuss more fully later

2 In Group 2 we can place those cases in which the detonation of high explosives has caused wounds and injuries of the body, including the central nervous system, which have not been immediately fatal The number of these cases which do not exhibit any of the functional disorders and disturbances characteristic of what is termed "shell shock" without visible injury, although such individuals have received most serious and fatal wounds from exploding shells, leads one to consider that in a large proportion of cases of shell shock without visible injury there are other factors at work in the production of the nervous symptoms besides the actual aerial forces generated by the explosive

3 The third group includes injuries of the central nervous system without visible injury, and to this group I shall give especial attention, as it is the one of which I have had most experience I include the functional neuroses and psychoses because although there may be no discoverable lesion in a "psychic trauma," yet so complex is the structure of the human central nervous system, and so subtile the chemical and physical changes underlying its functions, that because our gross methods of investigating dead material do not enable us to say that the living matter is altered, yet admitting that every effect owns a cause, a refractory phase in systems or communities of functionally correlated neurons must imply a physical or chemical change and a *break* in the links of the chain of neurons which subserve a particular function As we know, one of the peculiarities of the functional neuroses is not only the sudden manner in which an emotional shock may engender a loss of function, but likewise the sudden manner in which it may be unexpectedly restored by a sudden stimulus of the most varied kind, provided there is an element of surprise That is attention is for a moment taken off its guard I am referring especially to *mutism* The causes of shock to the nervous system by high explosives may be considered under the headings of physical trauma—concussion or 'commotio cerebri' by direct aerial compression or by the force of the aerial compression blowing the person into the air or against the side of the trench or dug out or by blowing down the parapet or roof on to him causing concussion or a sandbag hitting him on the head or spine might easily cause concussion without producing any visible injury

Again, he might be buried and partly asphyxiated or suffer from deoxygenation of his blood by CO poisoning, for, as I shall prove later, these high explosives generate considerable quantities of CO which is inodorous and would not be recognised A man lying unconscious or even conscious and partially buried and unable to move would be very liable to be poisoned by CO and not know anything about it, nor would the rescuers, as the poisonous effects of the gas depend upon the amount in the atmosphere and the length of time to which the individual is exposed to it

A Brief Survey of the Dynamic Conditions of the Central Nervous System, especially in Relation to the Cerebro spinal Fluid and Shock

The whole central nervous system is contained in a closed space, the walls of which are formed by the cranium and spinal column, inside of which is the stout dura mater Within this closed space is the cerebro spinal fluid, which fills up all the space not occupied by blood vessels or tissues The cerebro spinal fluid thus serves to equalise the pressure throughout the whole cranio spinal cavity, moreover, at the base of the brain where the vital centres of the medulla are situated it acts as a water cushion, protecting them from the shock of commotion and concussion The cerebro spinal fluid also serves as a self adjusting mechanism by maintaining a uniform equalisation of the blood supply to the nerve elements during the rhythmical variations of respiration and circulation Now this fluid is incompressible, and under ordinary conditions of pressure from without it serves as a perfect protective mechanism but when large quantities of these high explosives are detonated an enormous aerial compression is instantly generated and it is quite possible that this may be transmitted to the fluid about the base of the brain and cause shock to the vital centres of the floor of the fourth ventricle, causing instantaneous arrest of the functions of the cardiac and respiratory centres Lord Sydenham, one of the highest authorities on the dynamics of explosives, concludes that the forces generated are sufficient to cause instantaneous death, and he has informed me that in the American Medico Military Report it is stated that ' an aneroid showed that the explosion of one of these shells caused a sudden atmospheric depression of about 350 mm of the mercury tube, corresponding to a dynamic pressure of about 10 tons to the square yard One effect of this is to liberate nitrogen suspended in the blood and transform it into bubbles of gas which are driven into the capillary vessels and cause instant death The writer, Surgeon Fauntleroy, is not satisfied with the explanation which "does not take into account the primary air compression by which men are sometimes hurled into the air" He (says Lord Sydenham) considers as I do, that the blow on the body, especially over the heart and abdomen, may cause instant death I have had officers under my care who have been blown in the air considerable distances One Royal Army Medical Corps officer told me he was blown 30 feet another told me that he was blown a considerable distance in a communication trench and lost consciousness for some time, another told me that the effect was like a violent push of irresistible force with a down cushion But I shall have occasion later to refer to this explanation of sudden death when considering the various theories regarding the cause of death of groups of men found in postures and attitudes of the last act of life If aerial concussion by the forces generated by high explosives can cause death without visible injury, I think more probably it would arise from sudden arrest of the medullary centres The stem of the brain surrounded by the cerebro spinal fluid is prevented from oscillating by the nerves which issue from it to pass through the holes in the skull, likewise the spinal cord by the anterior and posterior roots and the ligamentum dentatum is prevented from oscillating A sudden shock of great intensity would be transmitted through this incompressible fluid, and seeing that it not merely surrounds the central nervous system but fills up the ventricles and central canal and all the interstices of the tissues serving as it does the function of lymph it follows that a shock communicated to the fluid of sufficient intensity would make itself felt on all the neurons

The Neuron Doctrine in Relation to "Shock and the Theory of Diaschisis

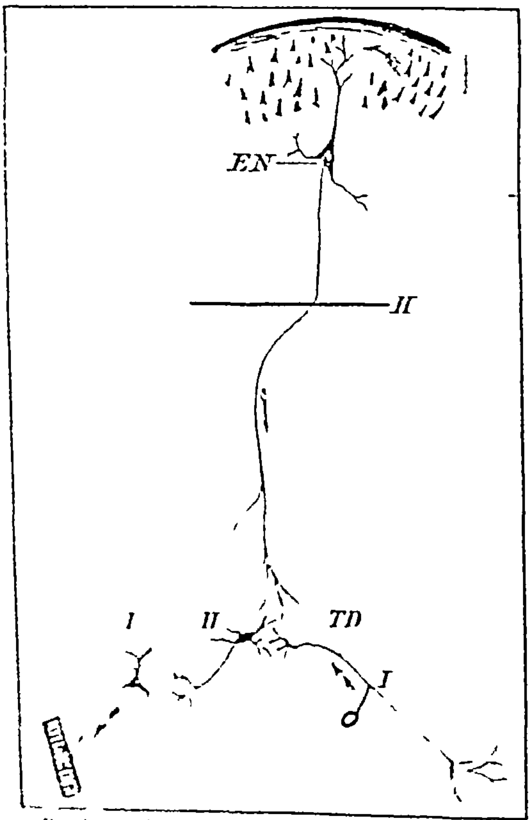
The central nervous system consists of innumerable anatomically distinct nervous units Each consists of a cell with branching processes there is one process the axon, the remaining processes are termed dendrons The axon and dendrons are conductile, the chemical changes incidental to nervous action almost entirely occur in the cell There are two types of neurons the first type of Golgi, in which the axon leaves the grey matter to become surrounded by a myelin sheath to enter into the formation of the white matter, and the second type, in which the axon never leaves the grey matter, these are the intercalary neurons They always intervene between neurons of the first type and in the cerebral cortex they form definite layers especially well developed in the sensory projection centres—e g, of vision and hearing I will endeavour to show how retraction of the branching processes of these intercalary cells would shut off consciousness of the external world These intercalary neurons possess only a small amount of cytoplasm, and are therefore unable to store oxygen Sudden failure of the heart's action by shock, whether of physical or emotional origin, lowers the oxygen tension in the tissues and a dissociation of the sensory projection neurons from the cortical perceptor neurons occurs

The whole of the neurons of the central nervous system may be primarily divided into these two groups 1 Neurons of the first type which may again be divided into sensory or afferent projection motor or efferent, and association neurons 2 Neurons of the second type or intercalary To take a few typical examples of the influence of shock affecting one part of the central nervous system being transmitted through anatomically and functionally correlated neurons to remote parts In hæmorrhage into the internal capsule we have sudden irruption of blood cutting through the pyramidal efferent system of fibres resulting in flaccid paralysis of the opposite limbs (Fig 1) the shock effect has been transmitted to the intercalary neurons at the base of the posterior horn of the spinal cord, and for the time being it has suspended the normal reflex tonus, that is to say dissociation of the sensory projection fibres of the reflex arc has occurred But we know that as soon as the shock effect has passed off a spastic condition supervenes on the flaccid The reason of this is that the normal inhibitory cortical influence has been interrupted and association of the sensory afferent and motor efferent in the reflex arc having been restored by a return to normal function of the intercalary neurons, the reflex tonus is increased by withdrawal of the cortical inhibitory influence Let us take another example of which I have seen several a bullet wound of the occipital region of the skull causes complete blindness, but not deafness After a time the patient is left with hemianopsy, the fact that the wound did not produce deafness shows that it was not general shock to the brain that led to the opposite occipital lobe being temporarily put out of function (Fig 2) The two occipital lobes are anatomically and functionally correlated, and the injury of one lobe caused a functional dissociation by the shock effect transmitted through the association fibres of the splenium This temporary dissociation by shock of anatomically and functionally correlated systems of neurons has been termed by Monakow diaschisis

THE LIVING NEURON IN RELATION TO SHOCK

The researches of Ross Harrison on the living neuron and its growth render it possible to accept as a provisional hypothesis the theory of attraction and retraction of dendrons as an explanation of association and dissociation The intercalary neurons may indeed possess amœboid movement A study of the living neuron shows that totally erroneous ideas may arise if we are guided by the appearances presented by the neurons in sections

FIG 1



[illegible] neuron of voluntary motor [illegible] in internal capsule [illegible] terminals in [illegible] Temporary [illegible]

after they have been submitted to hardening and fixing reagents Especially is this so in respect to the effect of shock by concussion caused by high explosives The remarkable observations of Colonel Gordon Holmes on gunshot injuries of the spine causing concussion of the spinal cord without penetration by the projectile of the dura mater, show the importance of a consideration of the living neuron The force of the concussion he shows produces most extraordinary changes in the axons which become enormously swollen

FIG 2

The condition of the nerve cell may be studied in sections by two methods, in one of which fibrils can be demonstrated by the silver method of Ramon y Cajal, the other by which a basophile staining substance (the Nissl granules) forms a pattern around the nucleus The neuron when damaged by injury or disease shows various changes in the appearances of the cells whether the fibril method of staining be adopted or the Nissl granule method—e g, if the processes of the cell be cut the living neuron is wounded and the body of the cell after it has been killed by the process of fixation and hardening exhibits changes, likewise if the neuron has been damaged by a poison changes are seen, but there is nothing specific about these changes—e g, one could not recognise any difference in the perinuclear chromatolysis of lead encephalitis, alcoholic psychosis experimental anæmia and section of the axons of nerve cells The Nissl granules of basophile substance, as I pointed out in the Croonian lectures 1900[1]—"On the Degeneration of the Neuron"—do not exist in the living cell Nevertheless the amount of this basophile staining substance in the form of Nissl granules may be regarded as evidence of the amount of energy substance (neuro potential) which the cells possessed during life (Fig 3) In the healthy cell it is continually undergoing disintegration and automatic reintegration When the cell is damaged metabolic equilibrium is no longer maintained and its osmotic surface tension is altered and water passes into the cell causing it to swell, displacing the nucleus and causing an appearance of chromatolysis But this basophile staining substance which forms the Nissl granules does not exist as such in the living cells If the living nerve cell be examined by direct illumination no Nissl bodies are seen in the cytoplasm only fine dark granules like an emulsion (Fig 4) If living cells are examined microscopically with dark ground illumination (Fig 5) they are seen to be filled with small granules or globules, each of which after escaping from the cell remains discrete They are refractile and appear white and luminous, this is due to a delicate covering film of a lipoid substance which encloses a colloidal fluid, probably consisting of a solution of salts and cell globulins When the cell dies this colloidal fluid is coagulated and the precipitated proteid substance is massed together into little blocks—the Nissl granules, the intervening denser colloidal substance is continuous with the colloidal substance of the axon and dendrons The film that covers each globule is stainable by vital methylene blue, and a living nerve cell stained by vital blue represents the appearance of an emulsion of minute faintly blue globules If the living cell thus stained be kept in an atmosphere of nitrogen in a warm chamber the stored oxygen is used up and a leuco base is formed, causing the globules to lose their colour, the cell appearing of a greenish tint On admission of oxygen the living cell again becomes blue It thus appears possible[*] that these granules represents a large oxygen surface, like spongy platinum, within the cell When the cells die the lipoidal film of the globulin containing fluid is destroyed, coagulation occurs, and the Nissl granules are formed These facts accord with the knowledge that stimulation of a piece of nerve causes practically no metabolic change or using up of oxygen, therefore the mere conduction of a stimulus along a nerve does no entail loss of neuro potential The chemical processes incidental to the using up of nervous energy in the neuron take place in the cell itself, and for this reason it is that the blood supply of the grey matter is six times that of the white matter In all active neural processes oxygen is used up and carbonic acid is produced which escapes into the circumambient cerebro spinal fluid One stimulu differs from another that is discharged into a cell by variation in modes of motion and it is conceivable that the granules which fill the cell are sensible to the varying modes of motion and a

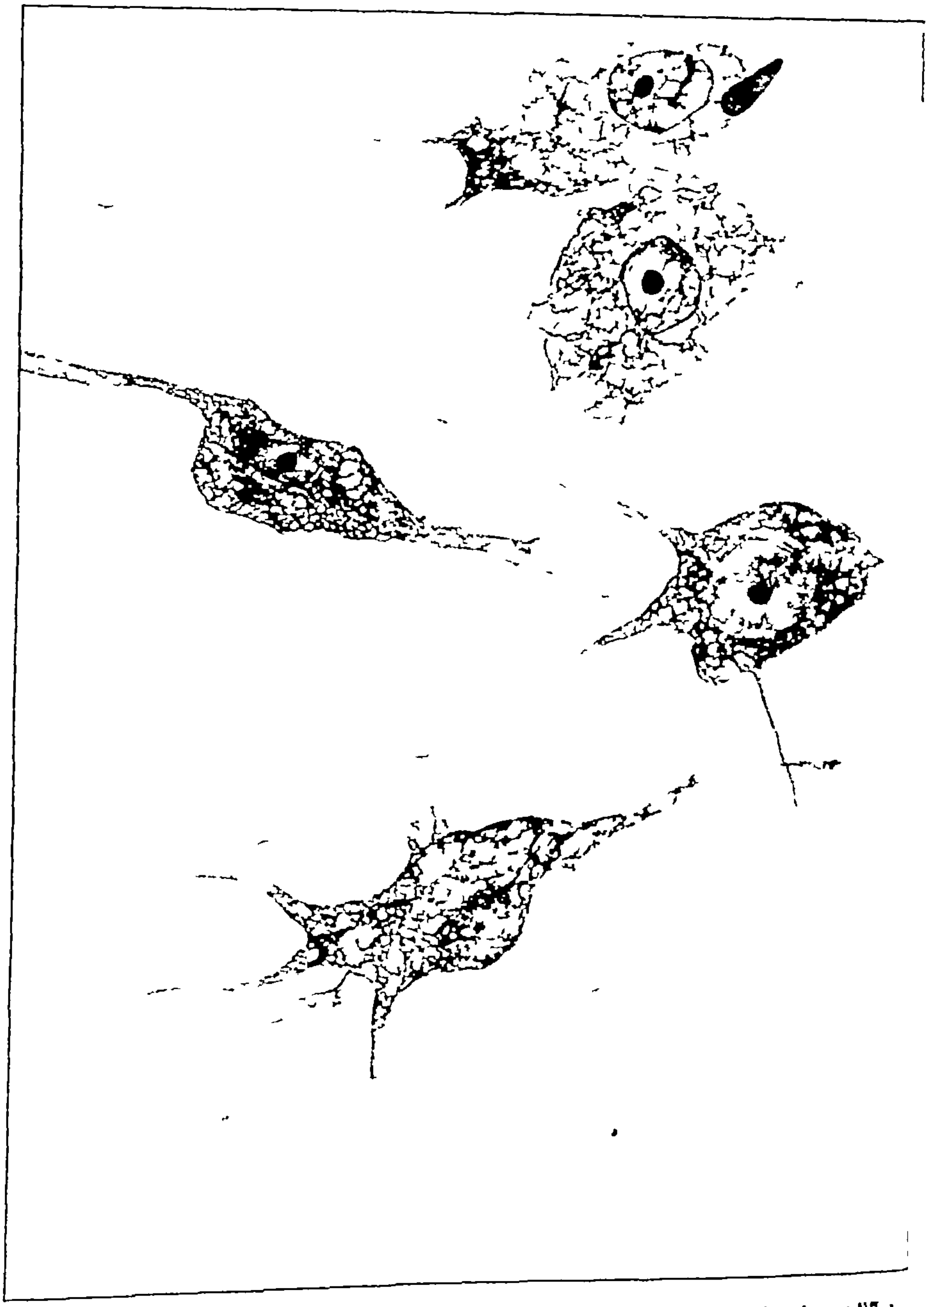
FIG 3

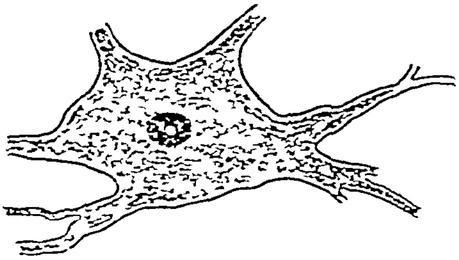


Five cells from a case of a man who lived eight hours after receiving an electric shock of 20 000 volts A very dif chromatolysis with loss of basophile staining substance thereby revealing the intracellular and intranu networks is observed Polychrome staining Magnification 810 oft-repeated stimulus suffices by the establishment of a biorhythm in the cell to pass through to the intercalary neuron with little expenditure of neuro potential, whereas a new stimulus which requires a concentration of attention must be either transformed or reinforced before connexion of the terminals of Neuron I with Neuron II (see Fig 1) can take place, and this involves a using up of neuro potential Severe concussion can not only cause immediate dissociation of the cortical perceptor neurons, producing unconsciousness or a disturbance of conscience, but for a varying period of time it can destroy the power of recollection of perceptions prior to the shock. There is a retrograde amnesia and in very severe cases of shell shock, as I shall point out later, there may be a complete loss of memory both as regards recollection and recognition. The loss of recollection may be attributed to dissociation of the higher association systems of

---

[*] The experiments relating to the living cell were commenced before the war and I have not had time or opportunity to prosecute this research further I therefore put forward this hypothesis tentatively

FIG 4



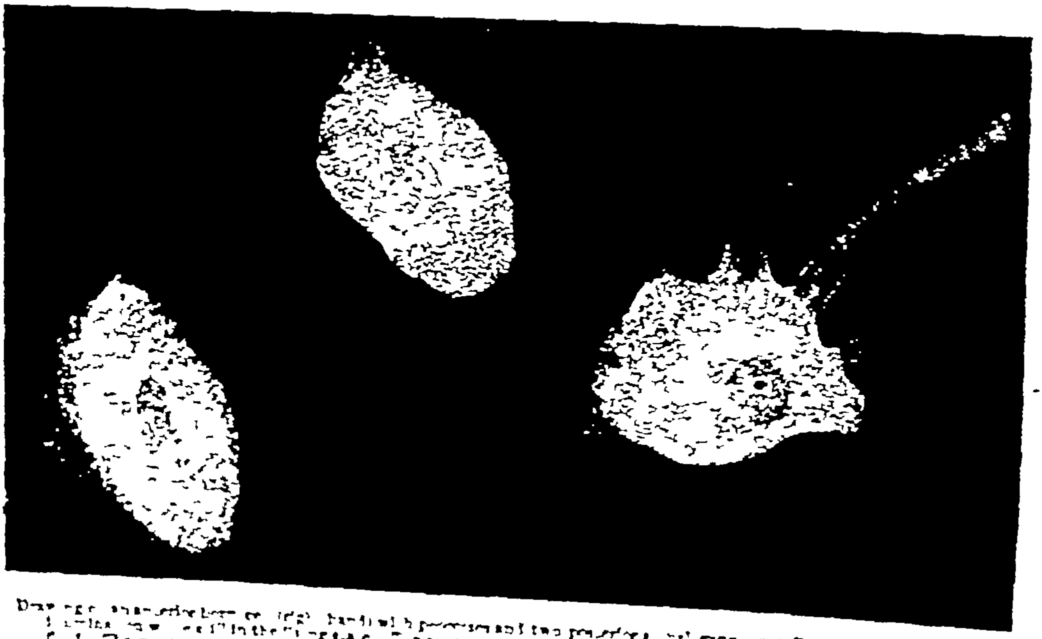
An anterior horn cell of spinal cord examined immediately after death by direct illumination. The grey matter was teased in cerebro-spinal fluid and the preparation examined on a warm stage The cell is seen to possess no Nissl bodies, but is filled with dark granules like an emulsion. (Obj 4 mm oc 4)

from the perceptor systems of neurons Functional blindness and deafness which often persist when consciousness returns may be due to one afferent system remaining dissociated

But why, it may be asked, do we find varying degrees of retrograde amnesia associated with loss of recollection of recent experiences, while those of earlier life may be preserved? Shock so severe or toxic influences such as alcohol do not cause dissociation of the neurons in which habitual actions by frequent repetition have been registered and their revival requires a much less expenditure of neuro potential the more they have become habitual and instinctively automatic For the same reason the earlier experiences have been stored in memory, the more do they form the foundation upon which associative memory rests, for consciously and unconsciously these early experiences have been exerting continually their influence on the subconscious mind by association, and at the same time they have determined and been correlated with habitual and instinctive actions, requiring but little conscious effort and expenditure of neural energy

The delicate granules filling the nerve cells have been termed "neuro bions," as if they were independent living units, but this is *theory* *It is*, however, conceivable that violent concussion transmitted to the cerebro spinal fluid which forms the circumambient medium of such a complex mechanism as the living nerve cell, could cause a violent oscillation of these neuro bions and a loss or disturbance of their functions of variable duration according to the severity of the shock I show here (Fig 3) the appearance presented by the cells of the medulla of a man who died eight hours after receiving a shock of 20,000 volts

FIG 5



[illegible] anterior horn [illegible] cells as seen by dark-ground [illegible] the tissue in warm cerebro-spinal [illegible] In this way the living cells can be observed

[illegible] pyramidal neurons which form a sheet of cells or [illegible] layers covering the whole cortex cerebri The loss of recognition may be attributed to a dissociation between the cortical perceptor systems of neurons and in complete loss of consciousness of the external world there is dissociation of all the afferent projection fibres of subcortical neurons

OXYGEN AND CONSCIOUSNESS

It is known that a *continuous* supply of oxygen is essential for consciousness The bulk of the cortex is supplied by the internal carotid arteries, compression of these arteries causes loss of consciousness in about five or six seconds Histological investigation tends to show that the intercalary neurons have no store of oxygen in their cytoplasm, they depend, therefore, upon a continuous renewal of the oxygen in the circumambient fluid, consequently as soon as the capillary circulation ceases they feel the effect of lack of oxygen and cease to function, causing dissociation to occur Now a violent emotion such as fright can by its influence on the vaso motor centre and the heart's action, causing a fall in the blood pressure, produce an immediate lowering of oxygen tension in the fluid, and thereby suspension of function of the intercalary neurons of the cortex, followed by dissociation of the cortical perceptors and loss of consciousness In many of the disorders of functions and loss of functions of the central nervous system resulting from shell shock, using that term in its widest sense, there occur symptoms of cortical dissociation—e g, cortical blindness, deafness, mutism, and paralysis

The symptoms of headache, weariness, loss of power of concentration, irresolution, and mental fatigue constituting a neurasthenic condition so frequently found as a result of shell shock may be explained by the acquirement of the habit of drawing on the reserve of neuro potential, and being unable through insomnia or sleep disturbed by terrifying dreams, worry, and anxiety to restore the balance and return to the normal conditions of automatic renewal of nervous energy as fast as it is used Physical shock accompanied by horrifying circumstances, causing profound emotional shock and terror, which is contemplative fear, or fear continually revived by the imagination, has a much more intense and lasting effect on the mind than simple shock has Thus a man under my care, who was naturally of a timorous disposition and always felt faint at the sight of blood, gave the following history He belonged to a Highland regiment He had only been in France a short time and was one of a company who were sent to repair the barbed wire entanglements in front of their trench when a great shell burst amidst them He was hurled into the air and fell into a hole out of which he scrambled to find all his comrades lying dead and wounded around He knew no more, and for a fortnight lay in hospital at Boulogne When admitted under my care he displayed a picture of abject terror, muttering continually "no send back,' "dead all round,' moving his arms as if pointing to the terrible scene he had witnessed

THE NATURE OF HIGH EXPLOSIVES AND FORMS OF PROJECTILES

Sir Anthony Bowlby in the Bradshaw Lecture on "Wounds in War' [3] called attention to the nature of high explosive shells and their terrible effects "These shells vary in weight from a few pounds to about a ton, and they consist of a thick iron case containing in a central cavity a violent explosive charge The latter is in the case of German shells trinitro toluene, and may contain as much as 200 pounds of this explosive Such shells are burst upon percussion by a detonator which acts by the impact of the shell upon the ground or on some other object These shells do not contain bullets, and the injury they do is in chief part by the jagged fragments into which they are split by the explosion, and also to some extent by the impact of portions of buildings such as stones or bricks which are scattered with immense force by the violence of the explosion [He might have added sandbags forming the parapet of a trench or the roof of a dug out] The fragments of the shells are always very rough and jagged and of every variety of size and shape For example, the base of a 17 inch shell may weigh 150 pounds, and if it struck the body of a man would completely destroy it Other fragments may weigh a few pounds and may tear off a limb or crush it to pulp, while in the smaller shells there may be scores of fragments about the size of the end of the finger or much smaller It must also be borne in mind that the mere explosive force of the gases of a large shell exercises great powers of destruction The expansion of the gases is sufficient to kill, and in the only case in my experience in which an autopsy has been made the brain was the seat of very numerous petechial hæmorrhages" This brain, by the kindness of Professor Arthur Keith, has come into my possession and the result of the microscopic examination I shall deal with fully in my next lecture Suffice it to say that the appearance it presented led me to suspect CO poisoning But high explosives are used also in mines, and in various other forms of projectiles such as aerial torpedoes, whizz bangs and grenades It is, however, the big shells and mines which are so deadly in producing fatal or serious effects on the central nervous system without visible external signs of injury

The following cases show the great force generated by high explosives

A lieutenant under my care told me that he was in a communication trench when an aerial torpedo exploded close to him He felt a great pressure against him, it was soft but sufficiently powerful to knock him down unconscious He did not know how long he was unconscious but thinks it must have been an hour When he recovered consciousness he got up and was helped away His head felt as if it would burst, and ever since he has had a whizzing in the left ear and dizziness Dreams of bombs and aerial torpedoes bursting There was no parapet to blow down on him

A captain in the R A M C told me that a large shell burst at his back, and he was blown 15 yards by the aerial disturbance

An R A M C officer at the battle of Ypres had a shell explode near him He was not hit, but lay unconscious for six hours He recollects the shock of the shell as he went out of the dressing room For some days he suffered with severe headache and soreness of back of head and down the spine, the lower extremities felt heavy but there was no loss of feeling He had retention of urine for a day only and around the body there was a pain like an appendix pain He rapidly recovered

THEORIES REGARDING CAUSATION OF INSTANTANEOUS DEATH OF GROUPS OF MEN

At various times, from the earliest periods onwards in the war journalists have given vivid descriptions of shell fire causing instantaneous death of groups of men Ashmead Bartlett in his graphic description of fighting in the Dardanelles relates what he found in A Valley of Death ' "In one corner seven Turks with their rifles across their knees are sitting together One man has his arm around the neck of his friend and a smile on his face as if they had been cracking a joke when death overwhelmed them All now have the appearance of being merely asleep, for of the seven I only see one who shows any outward injury How can we explain death without apparent bodily injury yet so instantaneous as to fix them in the life like positions and attitudes thus realistically described? Did rigor mortis come on immediately and what was the cause? Officers and soldiers have told me that they have felt ill and vomited with the gases generated by these high explosive shells A Canadian officer told me that in the first gas attack made by the Germans he felt ill and vomited with the gases generated by the high explosive shells The smell has, like that of bananas, a faint sickly odour that made him feel ill and vomit, and quite different to the "gas" In considering the causation *of fatal* shell shock without visible sign of injury it is necessary, therefore, to take into account chemical changes in the atmosphere together with the physical forces generated by the explosive The effect of the emanation of a poisonous gas was the explanation at first given *for instantaneous* death *without physical* sign of injury, it was widely bruited about that turpinite, a French high explosive, produced a deadly gas which would be quite capable of producing sudden death without visible signs of injury, but the question even then arises, Why should the body remain in a life like position? Many authorities regard it as much more likely *to be* due to the effects of concussion on the nervous system Cases that have recovered after severe concussion without visible sign of injury may, nevertheless, have received physical concussion by sandbags blown down from the parapet into the trench, or if the shell burst in a dug out, the earth may be driven down with great force, burying the inmates A case, however, came under my care, in which there was no history of this happening, from No 6 C C S, 24–25/9/15, as follows —

---

[3] THE LANCET Dec 25th 1915 p 1385

This man was blown up by a shell and was found in the dug out with his two comrades, both of whom were dead While here he has been quite insensible to all questions He has been in a *cataleptic* state, with at times convulsive seizures His light reflexes are present

He was removed *to* No 30 C C S I, and further notes state — Reflexes very active *Urine* drawn off 1 pint, when tested showed marked *albumin Both pupils widely* dilated Speaks incoherently occasionally There is *no outward evidence of any injury* or symptoms of pain anywhere *Five days later he was admitted* to the 4th London General Hospital He complained of a strange *feeling* in his head and sweated profusely He was terrified when the corporal in charge shook him to try and stop his shouting and rambling He complained of severe headache of the vertex shook a good deal and said everything in front of him *looked* blurred He could hear and comprehend what was said to him and spoke in reply to questions, subsequently he made a complete recovery

The fact that *there was albumin in the urine* when it was drawn off and *no visible sign of* injury suggests that inhalation of *noxious gases* in a closed space was an important contributory cause of the death of his two comrades and of the severe temporary symptoms which he *manifested* But it might be argued if *poisonous gases generated* by the explosion cause death it is only by *inhalation* while the man is lying on the ground unconscious or partially buried and this would not account for the sudden death where groups of men are found fixed in the last act of life M Arnoux

ground with great violence, but in the case of men leaning against the side of a trench wall only the static depression could affect them What, M Arnoux asks, would be the effect on the human organism of so *powerful* and so sudden a decompression? It would, he answers, be similar *to that* which *causes* the deaths of aeronauts who make too rapid an ascent or of workers in compressed air caissons who leave their caissons *too* quickly and without taking proper precautions for their slow decompression—namely, the sudden escape from the blood of bubbles *of air and* CO_2 which would produce capillary embolism throughout the *body* and cause sudden *death* M Arnoux's *theory* is, then, that the *sudden increase* of atmospheric pressure produced by the explosion is capable of producing an immediate increase and absorption of air and CO_2 *followed by a sudden liberation* on return to normal conditions

Surgeon General Stevenson,[4] commenting upon the theory of M Arnoux, asks "Is it possible that a sudden increase of atmospheric *pressure*, lasting only a *fraction of a second, no matter* how great it might be, *could so charge the blood* with gases that their discharge into the *blood stream* when the pressure ceases would cause death in the same manner as a too rapid return to ordinary atmospheric pressure in caisson workers?" *He advocates* the theory of concussion of *the central nervous* system as the most satisfactory *explanation*, the water jacket of the cerebro *spinal fluid serves as a pro*tection to the vital centres of the medulla under all ordinary conditions of *commotio* cerebri But in *these cases (as M Arnoux s experiments prove)* we are dealing with *extraordinary* conditions of atmospheric pressure a pressure force which we believe is sufficient to cause a temporary loss of consciousness, temporary blindness, deafness, paralysis, and loss of speech without any *visible signs of injury* If the functions *of the higher centres are for* a time instantaneously *suspended by the shock, it is* conceivable that in the severest cases the functions of the vital centres *of* the medulla *may be* instantaneously suspended by its concussion, *moreover, the hæmorrhages* in the corpus callosum and the basal ganglia found in the *brain referred to* might be explained by the fact that the ventricles are *filled* with incompressible fluid to which the violent shock is transmitted

The cases that have recovered after *severe shell* shock very rarely show signs or symptoms of organic disease

But suppose the air is charged with *carbon monoxide* and oxides of nitrogen, would it *not* be *possible* for the man to inspire enough of these *gases to cause* instant death? I wrote to Professor *Leonard Hill* on this subject, and I received the pressure will be equally distributed through the fluids of the body in all directions, and it is not enough to break the thoracic wall by the sudden compression of the gas in the lungs A copper ball with a glass tube sealed up full of air sunk in the deep sea is broken in when the glass tube bursts in spite of a free opening into the copper ball I imagine the thoracic wall might be broken in by a sufficient sudden pressure The elasticity of the atmosphere is such that this does not occur I once carried out some experiments on the effect of exploding heavy charges of gun cotton on pigs A few feet of air was enough to save the pigs from damage When the gun cotton exploded near the ground the soil, stones, &c , were converted into missiles and these wounded the pigs The lungs of these pigs showed some patches of emphysema, as if the sudden wave of air pressure had driven air from one part of the lung into other parts

I should say the men either die, as you suggest from the gases—deoxygenation of blood—or else from concussion

Also through Lord Sydenham I have heard from the secretary of the Trench Warfare Department that it is possible that the partial detonation of a large shell containing, say, 50 to 100 lb of T N T would produce enough carbon monoxide in the immediate vicinity to give rise to the characteristic poisonous effects of this product

PART III *—THE ELECTRICAL RESISTANCE THERMOMETER

IN 1901 Professor Benedict and Dr John Snell published[74] a series of observations on the temperature of the human body measured by means of an electrical resistance thermometer, a form of thermometer now largely used in pyrometer work by Callendar, Feré, and others The method employed was not absolutely automatic or continuous as the electrical circuit had to be closed by hand every minute and the deflection of the galvanometer noted Referring to this method Gamgee remarks —

> Admitting as I *do that Professor Benedict's* observations possess a very much higher value than any which preceded them, I still think that his method left the problem of the automatic registration of the temperature of man unsolved

Three years earlier than this (1898) Adami, who desired to make observations on the diurnal variations of the temperature of the human body, suggested to Professor H. L Callendar,[75] then of Montreal, but afterwards of London, where he collaborated with Gamgee, that he should devise electrical resistance thermometers similar to those used in the pyrometer but specially adapted for recording the temperature of different parts of the animal body

In 1904 Ronald Ross,[76] using a resistance thermometer and recording outfit placed at his disposal by the Cambridge Scientific Instrument Co , obtained 24 hour record temperature curves, a couple of which he publishes He gives the curve, however without marking the temperature at any point except in terms of axillary temperature taken with the clinical thermometer There is no standard therefore for the rectal temperature except that obtained from a comparison with the axillary temperature His curves are, however, of interest as indicating that this method of recording temperatures had now reached the hands of the medical man, having been passed on from the physicist

At the same time similar work was carried on in Germany, and Siemens and Halske constructed an electrical resistance thermometer with switchboard and recording apparatus, the galvanometer needle making a tracing on the flat This apparatus was in many ways admirable, but it had the disadvantage that the record was in the form of the segment of a circle with a radius of the length of the galvanometer needle or lever In 1911 and 1912 Drs Eichler and Schemel[77] published a couple of papers on work done with an improved recorder in which a pointed chopper bar and inked ribbon method of obtaining a dotted record was used The records obtained with this apparatus are excellent

In planning out our work on the temperature of bovine animals in health and disease we soon came to the conclusion that the thermo electric couples above described were too delicate in their construction and required the use of too complicated apparatus We determined, therefore, to adapt the resistance thermometer to our requirements and to use a thread recorder with a stronger phosphor bronze wire suspension, a much more robust instrument than that provided with the delicate suspension essential for use with the thermo electric couple thermometer A switchboard for standardising and fixing the range of temperature was also used With this apparatus we were so successful in obtaining accurate temperature records from animals † that we decided to adopt it for work in the wards, and one of us (P C V J) undertook to adapt the resistance thermometer to the human subject, a thermometer with which all our later work has been done

DESCRIPTION OF NEW OUTFIT

Our new outfit may be considered under the following heads (1) The electric resistance thermometer and its leads, and (2) the switchboard for standardising the recorder by fixing the range and limits of temperature

The thermometer constructed for us by the Cambridge Scientific Instrument Co is a Callendar Griffiths platinum electrical resistance thermometer with certain modifications, the outcome of our experience The essential part of this instrument is a fine platinum wire wound round a couple of strips of mica (Fig 14) notched at both sides and so arranged that they form an elongated frame into the notches of which the coiled platinum wire drops, and is held in position This coil, on its frame, is enclosed in a silver (an excellent conductor) tube, which lies close up to, without coming into actual contact with, the wire

The thermometer coil is connected by comparatively heavy flexible leads, composed of a series of strands of copper wire to the Wheatstone bridge or instrument on which the resistance (and the temperature) is to be measured by means of the deflection of a galvanometer Parallel, and in addition, to these primary leads run two similar copper wires or dummy leads which, though in close proximity to the leads of the platinum coil, are joined at their ends near to, but independent of, this coil These leads are introduced into the side of the bridge opposite to the side to which the thermometer leads are attached, and act as "com pensating" leads (Fig 14 N), thus rendering the outfit practically independent of any changes in the length or temperature of the primary leads The two sets of leads simply throwing in or with drawing equal resistance on both sides of the bridge, no error is introduced, and any length of leads may be used Beyond the actual thermometer part, the platinum wire coil, the leads are held together by, and covered for some distance with, a length of rubber tubing (Fig 14)

---

* Parts I and II were published in THE LANCET Jan. 22nd (p 173) and Feb 5th (p 231) respectively

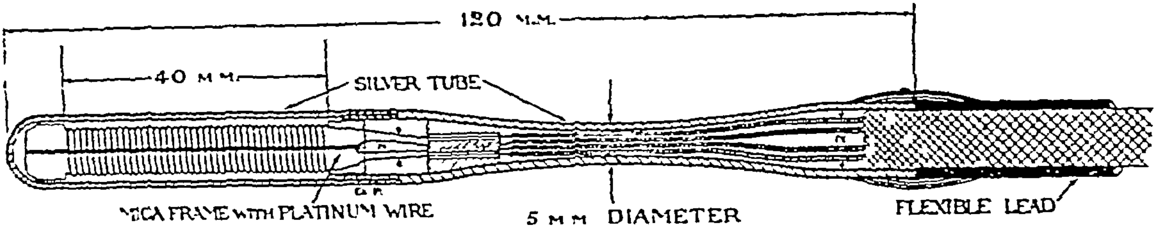
† Journal of Comparative Pathology and Therapeutics Edinburgh and London 1915 vol xxviii pp 337-357

The electrical resistance of the platinum wire varying with the temperature in a very definite manner according to a well known law ‡ it is possible, by measuring this resistance, to determine the temperature to which the platinum, which thus acts as a thermometer, is brought, the variations of resistance and therefore of temperature being registered automatically by the recorder The current used is supplied by a 4 volt accumulator with which an adjustable rheostat is in series This accumulator is thrown into the circuit by being placed across two arms of the bridge (Fig 15)

A skin thermometer, up to the present applied only experimentally, consists essentially of a coil of fine platinum wire of definite and known electrical resistance wound on a silver backing about 1¼ in square and heat insulated from it The platinum is embedded in a "shellac"-ed surface which is intended to be laid flat on the skin, thereby afford ing fairly intimate contact and at the same time ensuring good electrical insulation and immunity from mechanical damage to the wire The silver back has two small silver lugs provided for fixing a holding strap if required The thermometers are supplied with their respective resistance coils, making them interchangeable and enabling them to be used on the same recording instrument as the rectal thermometers Into the leads of each thermo meter a suitable rheostat is introduced with this arrangement any thermometer may be used and all become interchangeable

The recorder is illustrated in Fig 13 the box containing the bridge coils with the plugs and [illegible]

FIG 14



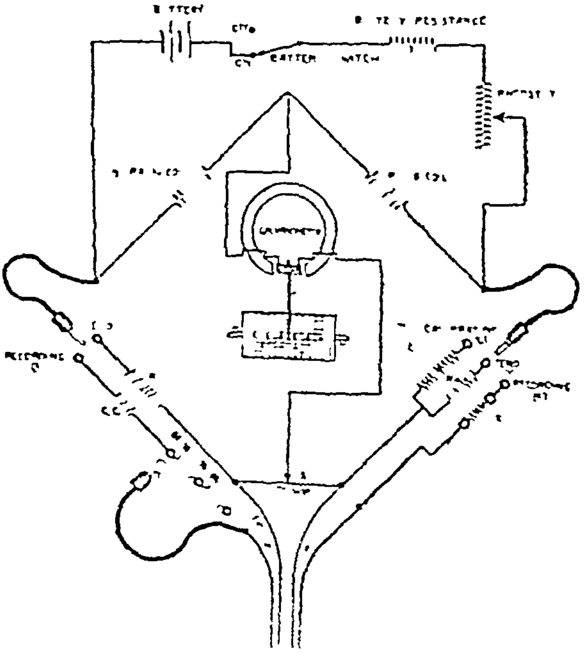
Section of resistance thermometer as used for human subject (to scale)

When the thermometer coil is heated the bridge is thrown out of balance and the galvanometer needle deflected, the deflections over a small temperature range being proportional to the amount the bridge is out of balance—that is to say, to the amount of increase in the resistance of the thermometer coil with a given change in temperature

TESTING THE RESISTANCE

In order to obtain correct temperature readings it is necessary to standardise the thermometer This is a simple procedure and can be done rapidly With the switch off—i e, before any current is passed through the apparatus—the mechanical zero of the galvanometer must be determined The needle should hang at rest at the outermost line (say 96°F) at the lower end of the record If it is not in this position the torsion head, Fig 11 D and Fig 12 D, from which the galvanometer coil is suspended is rotated until the needle hangs on the line This done, the electrical zero should be fixed With the switch still "off" the two plugs shown on the right and left hand sides of the diagram

FIG 15



needle does not then hang correctly it shows that there is too great a resistance on one side or other of the bridge This is corrected by moving the slider (S) right or left on the slide wire (Fig 15, S) A small movement of this slider (or slight rotation of the button in the centre of the switchboard, Fig 13) should bring the galvanometer needle to the correct position—viz., 96°F

The next operation is to test whether the galvanometer needle (E) is deflected correctly for a definite change in the resistance of the circuit This might be done by warming the thermometer, but experience has shown that this is a long process, especially if accuracy be aimed at The simplest plan, therefore, is to introduce a manganin resistance equal to the change in resistance of the thermometer for a definite number of degrees of temperature In practice the equivalent of a change in temperature of 10° F is used Turn the switch off and shift the plug on the right hand side of the diagram from the zero position to that of the calibrating position L and pull the switch "On" This introduces a resistance equal to R, plus a resistance equivalent to a change in the resistance of the thermometer coil for 10° F The galvanometer needle should now be deflected till it marks 106° F If it is not, then the current flowing through the battery circuit is insufficient, and the position of the slider on the battery rheostat must be altered to increase the current passing through the galvanometer until it is deflected through a larger angle—viz, through the equivalent of 10° F on the paper If too large a deflection is given the slider should be moved in the opposite direction in order to reduce the current in the circuit These adjustments having been made, the two plugs are shifted into the recording positions K and K′, and the instrument is ready for use and should operate correctly and without difficulty

The ranges in temperature are varied by means of the travelling plug shown in the compensating leads circuit If a temperature range across the paper from 88° to 98° F is desired the plug is inserted in the plug hole marked 88–98° If a higher range is required the plug is inserted in either of the two other plug holes marked 96–106° and 102–112° respectively (Fig 15)

METHOD OF USE OF APPARATUS

This apparatus, then, consists essentially of (*a*) a platinum wire through which can be passed a constant electric current provided by (*b*) a 4 volt accumulator This current, after passing through the platinum wire, is sent through (*c*) a galvanometer, the deflection to right or left of the galvanometer needle marking the diminished or increased resistance of the platinum wire as the result of change of temperature of that wire The accessory apparatus serves to regulate and standardise the current and to alter the excursion of the galvanometer needle in order that the zero may be fixed and the range of the temperature record adjusted

On studying the diagram (Fig 15) carefully the connexions of the instrument are readily understood and it is an easy matter to take a record Level the apparatus The galvanometer needle should then be at zero before the battery current is thrown in To test this, unclamp the galvanometer needle by turning key, N (Figs 11 and 12) (or in another model move the lever) at the back of the galvanometer which regulates the torsion of the spiral phosphor bronze wire suspending the needle Fix a chart paper on the drum with the numbered side close up to the shoulder at the gear wheel end of the drum, start the clocks and release the fly wheel, G, and the presser bar nipping the inked thread against the paper, a dot is made If this dot falls on the zero line the apparatus is accurately adjusted, if not, the needle should be adjusted by means of the screw as described above This movement is extraordinarily sensitive and requires some considerable care in its use, but once the correct zero is obtained there should, under ordinary conditions, be no further demand for adjustment

When standardising the current take care to keep the battery fully charged With the battery so charged the current is thrown into the circuit, but not into the leads, by inserting plugs at I zero and I′ zero Throw the switch lever "on" to complete the battery circuit, when the needle should remain at zero If the galvanometer needle is not at zero too much or too little current is passing through the circuit, and this must be counterbalanced by the rheostat The next step is to find the excursion of the needle The current is switched "off" and the two plugs are inserted at I zero and L, when the needle should travel the full length of the scale 10°F but no more If it fails to do this the needle must be brought to the correct position by means of the small sliding resistance (S)

Before making any of the above connexions take great care always to change the lever to "off" otherwise the whole current passing through the galvanometer causes violent deflection of the needle and "strain" of the coil and diminution of its sensitivity may result

The apparatus is now ready for the taking of a record Having inserted the thermometer, slightly warmed, into the rectum, the plugs are inserted at K and K′, the current is switched "on" and the clock started This should be done as soon as the thermometer has had time to register the temperature of the body—about 5 minutes

(*To be continued*)

ROYAL UNITED HOSPITAL BATH—The annual meeting of the subscribers to this hospital was held on Jan 31st The medical report was satisfactory but the financial statement showed a deficiency on the year of over £2000 The chairman (the Mayor) stated that Bath had raised about £25 000 for war funds but the committee hoped that at the termination of the war it would be possible to place the charity again in a sound financial position

DR WILLOUGHBY MASON WILLOUGHBY, the deputy medical officer of the Port of London and for [illegible] boarding medical officer has been appointed by the City Corporation to succeed the late Dr Herbert Williams as medical officer of health of the port

THE AERIAL CONVEYANCE OF INFECTION,

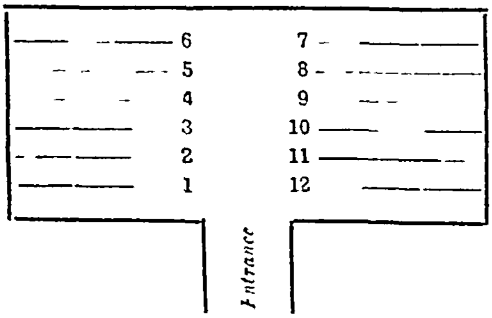
WITH A NOTE ON THE CONTACT INFECTION OF CHICKEN POX

By FREDERIC H THOMSON, M B, C M ABERD, D.P.H.,
MEDICAL SUPERINTENDENT OF THE NORTH EASTERN HOSPITAL, TOTTENHAM N

IN an article published in THE LANCET of June 13th, 1914 (p 1669) Mr Clifford Price and I recorded two years' work on the aerial conveyance of infection in certain fevers This work has been continued with increasing difficulty since the outbreak of war until Sept 29th, 1915, when it had to be stopped owing to shortage in the type of nursing staff, capable of the high standard necessitated, who could be spared for the work Shortly after the outbreak of war Mr Price was required for more important duties elsewhere, and I wish to record how deeply I am indebted to him for undertaking this work and sharing the heavy responsibilities with me

Since a continuation of the investigation has of necessity to be postponed, it seems a fitting opportunity to record the whole of the statistics from the commencement, while avoiding unnecessary repetition of the original article Once more I wish to express my great appreciation of the work of the nurses, and particularly of Sister Helen Turner, who continued in charge of the ward until it was closed

For a clear understanding of the position of the patients in the ward the following plan showing the disposition of the beds is necessary —



The space allotted to each patient is 195 square feet floor space and 15 lineal feet wall space Commencing Feb 12th 1912 497 patients were treated during a period of three years and somewhat over seven months As a number of these patients suffered from more than one disease the number of individual diseases is necessarily more and amounted to 657

1 septic † 3 septic [illegible] septic 3 septic § 2 infected in ward
* 9 infected in ward

Secondary Infections

All secondary infections that arose in the ward are called attention to below

1 *Scarlet fever* —256 cases of scarlet fever, including 11 secondary cases were treated in the ward and, in addition 2 cases which were infected in the ward. Of these 256 cases 146 were admitted during the first week of the disease and 110 at a later period One case of secondary infection occurred on Dec 2[illegible]th 1913, the other on the

following day, and both were left in the ward As suggested in the former article, the more likely mode of infection was the inadvertent admission of a nurse to duty in the ward who was suffering from a septic finger, and who consequently was unable to wash her hands thoroughly It is well, however, to record one doubtful secondary infection in January, 1915 This was a case of diphtheria and whooping cough which developed a rash resembling scarlet fever, but I regarded the rash as being the result of the serum treatment for diphtheria I admit the case may have been one of scarlet fever, and that I erred in my diagnosis, but the balance of the evidence was in accord with my conclusion

2 *Diphthera* —104 cases were treated. Of these, 51 were admitted during the first week of the disease and 53 at a later period. No secondary cases occurred

3 *Rubella* —41 cases of rubella were treated Of these, 32 were admitted on the first day of the disease, 6 on the second day, 2 on the fourth day, and 1 on or about the eighth day No secondary cases occurred

Several scarlet fever convalescents who had been exposed to rubella in other wards were admitted on the chance that they might develop the disease and so help to show if aerial conveyance would take place before the advent of the eruption None of these developed rubella Two of the nursing staff of the ward contracted the disease The first had the rash on April 10th, 1915 and she was on duty in the ward on April 8th The second developed the rash on April 13th, 1915 and she was on duty up to 8 A M on the 12th and not afterwards No infection arose from these contact exposures

On one occasion an opportunity arose of placing two first-day cases of rubella into the ward at the same time and advantage was taken of it On another occasion a first-day case and a second day case were placed in the ward at the same time

4 *Mumps* —23 cases of mumps were treated Of these, 16 were admitted on the first day of the disease, 3 on the second day, 2 on the third day, 1 on the fourth day, and 1 on the fifth day On two separate occasions two first-day cases were admitted at the same time, but no infection resulted from these double introductions One infection of mumps arose and the infected patient occupied Bed 7 There were two possible sources of infection One patient admitted on the first day of the disease occupied Bed 2, and another admitted on the third day occupied Bed 9 Counting from the first day of exposure the incubation period in the former case would have been 35 days and the latter 15 days If infection was aerially conveyed I favour the former source I am doubtful, however, whether this infection may not have been due to some fault in the nursing technique

5 *Whooping-cough* —75 cases were treated, including 2 infected in the ward Of these 34 were admitted during the first week of the disease including the two infected in the ward, 19 were admitted in the second week and the remainder at a later period of the disease Five cases of infection occurred all of which are described in the original article Since July 15th 1913, there has been no whooping-cough infection, although 48 cases have been treated since that date

6 *Measles* —No case of measles was knowingly admitted to the ward, but 2 cases admitted with other diseases were incubating measles Both were productive of secondary cases, as described in the original article

7 *Chicken-pox* —63 cases were treated including 9 infected in the ward Of the 54 cases introduced, 3 were admitted on the first day of the disease, 4 on the second day, 31 on the third day, 7 on the fourth day, 2 on the fifth day, 3 on the sixth day, 1 on the seventh day, 2 on the eighth day, and 1 on the tenth day The 3 cases admitted on the first day of the disease all had fresh crops of lesions afterwards and 1 was an infecting case This case had fresh crops of lesions until the fourth day and infected two patients The 4 cases admitted on the second day had fresh crops of lesions in two instances one a copious crop Three of these infected one patient each, the 2 with fresh crops after admission and one of the others Of the 31 cases admitted on the third day 4 had a fresh crop of lesions next day 2 of which were copious crops, 1 of the cases with a copious crop was in Bed 6 and infected the occupant of Bed 8 The other three cases did not cause infection Of the remaining 27, 2 proved to be infecting cases, and will be described below

A few of the earlier cases of chicken pox received "special nursing," which meant that the senior nurse on day or night duty was detailed off to look after the chicken pox case and was not allowed to touch any other patient except protected ones, and no other nurse was allowed to touch the chicken pox patient or anything connected with him

The 12th case was the last to receive "special nursing" therefore none of the undermentioned cases were so nursed.

19th case.—Bed 1 Third day, fresh vesicles on day of admission, but no fresh lesions in ward Eleven other cases in ward, 4 protected 7 unprotected. No infection.

20th case —Bed 1 Tenth day, scabs only Six other cases in ward, 3 protected, 3 unprotected No infection.

21st case —Bed 1 Third day, fresh vesicles on day of admission, but no fresh lesions in ward Eleven other cases in ward, 5 protected, 5 unprotected, 1 doubtful. No infection

22nd case.—Bed 1 Third day, fresh vesicles on day of admission, but no fresh lesions in ward Eleven other cases in ward, 6 protected, 5 unprotected No infection

23rd case —Bed 1 Third day pustules but no fresh lesions in ward. Nine other cases in ward, 3 protected, 6 unprotected No infection

24th case —Bed 1 Third day, fresh vesicles on day of admission and fresh crop day after admission Nine other cases in ward, 5 protected, 4 unprotected No infection.

25th case —Bed 1 Second day, vesicles few in number on admission and a fresh and copious crop day after admission Ten other cases in ward, 6 protected 4 unprotected Infected the occupant of Bed 11, who had been removed to another ward

26th case.—Bed 1 Second day, vesicles but no fresh lesions in ward Nine other cases in ward, 4 protected 5 unprotected. Infected the occupant of Bed 6, who had been transferred to another ward

27th case —Bed 1 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 3 protected, 7 unprotected 1 doubtful No infection

28th case.—Bed 1 Fourth day, scabs only, no fresh lesions in ward Eight other cases in ward, 4 protected, 3 unprotected, 1 doubtful. No infection

29th case —Bed 1 Third day, vesicles but no fresh lesions in ward Eight other cases in ward, 4 protected, 4 unprotected No infection

30th case —Bed 1 Third day, vesicles but no fresh lesions in ward Nine other cases in ward, 5 protected, 4 unprotected No infection

31st case —Bed 1 Third day, vesicles but no fresh lesions in ward Nine other cases in ward, 5 protected 4 unprotected No infection

32nd case —Bed 1 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 7 protected 4 unprotected No infection

33rd case —Bed 2 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 7 protected, 4 unprotected. No infection

34th case —Bed 1, Third day, pustules but no fresh lesions in ward Eleven other cases in ward, 5 protected 6 unprotected No infection

35th case —Bed 1 Third day, vesicles but no fresh lesions in ward Eight other cases in ward, 4 protected 4 unprotected No infection

36th case —Bed 2 Third day, fresh vesicles on day of admission and a fresh and copious crop after admission Eight other cases in ward, 4 protected 4 unprotected No infection

37th case.—Bed 3 Third day, vesicles but no fresh lesions in ward Nine other cases in ward, 4 protected 5 unprotected No infection

38th case —Bed 1 Third day, vesicles but no fresh lesions in ward. Ten other cases in ward, 2 protected, 8 unprotected No infection

39th case —Bed 3 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 5 protected 6 unprotected No infection

40th case.—Bed 8 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 5 protected 6 unprotected Infected the occupant of Bed 7 who had been transferred out of ward

41st case.—Bed 3 Third day vesicles but no fresh lesions in ward Eleven other cases in ward, 3 protected 8 unprotected. No infection

42nd case —Bed 10 Third day, vesicles but no fresh lesions in ward. Eleven other patients in ward, 2 protected, 9 unprotected No infection.

43rd case —Bed 6 Sixth day, scabs but no fresh lesions in ward. Nine other cases in ward, 2 protected, 7 unprotected. No infection.

44th case —Bed 8 Eighth day, scabs but no fresh lesions in ward. Nine other cases in ward, 2 protected, 7 unprotected No infection

45th case —Bed 5 Third day, vesicles but no fresh lesions in ward. Eleven other cases in ward, 2 protected, 9 unprotected. Infected the occupant of Bed 8 who was left in ward and in turn infected the occupants of Beds 6 and 9 No further infections

46th case.—Bed 7 Third day, vesicles fresh crop on day of admission but not in ward Eleven other cases in ward, 4 protected, 7 unprotected No infection

47th case —Bed 10 Third day, vesicles fresh crop on day of admission but not in ward. Eleven other cases in ward, 4 protected 7 unprotected No infection

48th case —Bed 4 Third day, vesicles but no fresh lesions in ward Ten other cases in ward, 5 protected, 5 unprotected No infection

49th case —Bed 4 Eighth day, scabs but no fresh lesions in ward Eight other cases in ward, 5 protected, 3 unprotected. No infection

50th case —Bed 9 Fourth day, vesicles but no fresh lesions in ward. Six other cases in ward, 2 protected, 4 unprotected No infection

51st case —Bed 1 Third day, vesicles fresh crop on day of admission but not in ward Eight other cases in ward, 4 protected, 4 unprotected No infection

52nd case —Bed 6 Third day, vesicles copious crop the day after admission to ward Eleven other cases in ward, 3 protected, 7 unprotected 1 doubtful Infected occupant of Bed 8 who had been transferred to another ward

53rd case —Bed 1 Third day, vesicles fresh crop on day of admission but not in ward Nine other cases in ward, 2 protected, 4 unprotected, 3 doubtful No infection

54th case —Bed 1 Third day, vesicles, fresh crop on day of admission but not in ward Nine other cases in ward, 2 protected 4 unprotected, 3 doubtful No infection

As stated above, 3 out of the 31 third day cases each caused one infection The first (Case 40) was in Bed 8 and infected the occupant of Bed 7 The second (Case 45) was in Bed 5 and infected the occupant of Bed 8 The third (Case 52) was in Bed 6 and infected the occupant of Bed 8

Case 40 was the twenty first case of the series introduced on the third day of the eruption, and the first 19 of the series were each placed next to a protected case or between two protected cases Case 39 was placed between a protected and an unprotected case, and Case 40 between two unprotected cases, and although 39 failed to infect, 40 did The bringing nearer to infection of the unprotected cases may reasonably be considered to add to the danger This course was persisted in until the ward closed, with the result that 6 cases of chicken pox had each been placed between unprotected cases 5 next unprotected cases on one side only and 1 between an unprotected and a doubtfully protected case The only infection was the one recorded above

The next third day infecting case (Case 45) I cannot satisfactorily account for This patient, who occupied Bed 5 was placed between two unprotected cases and did not infect either of them but did infect the occupant of Bed 8, directly on the opposite side of the ward It is to be noted that the occupant of Bed 6 escaped infection from Case 45 he was left in the ward as well as the occupant of Bed 8 from whom he contracted chicken pox Case 45 was not a patient from whom to expect infection for the total number of lesions was quite moderate and there were no fresh lesions on the day of admission or later the second crop having occurred on the day prior to admission to the ward It may be that the occupant of Bed 8 was a peculiarly susceptible child, and that the occupant of Bed 6 could withstand infection to some extent, but responded to a more powerful infection On the whole, however, I think that the occupant of Bed 8 was probably infected by indirect contact due to some error in the nursing technique I am the more disposed to take this view, knowing the difficulty of maintaining the nursing at the highest level at that time

The last third day infecting case (Case 52) might also be attributed to faulty technique, but I do not feel satisfied that such an explanation is justifiable, though the possibility must be admitted This patient was in Bed 6 and infected the occupant of Bed 8, not quite directly opposite, but failed to infect an unprotected child in the bed next to him Case 52 had a large crop of fresh lesions on the day following admission to the ward, which may very well account for the infection On the other hand, it must be remembered that three other third day cases had fresh crops of lesions on the day following admission (one of them a large crop), without causing infection Up to, and including, Case 31, only one third day case of chicken pox was introduced into the ward at the same time It was then thought desirable to introduce two third day cases at the same time if they could be procured This was done with Cases 32 and 33, and they were placed in Beds 1 and 2, and the same course was adopted with Cases 35 and 36 also in Beds 1 and 2 Finally it was done with Cases 46 and 47, who were put into Beds 7 and 10 In this instance two unprotected cases lay between 46 and 47, and another unprotected patient next to 47 on his other side No infection arose from these three double exposures

Comparatively early in the investigation, having introduced a number of third day cases without infection having arisen, I thought that the second day case, early in the series, which had produced infection, might have been exceptional, or possibly due to some error in technique Therefore, I introduced Cases 25 and 26 on the second day of the eruption However, both of these caused infection I subsequently commenced introducing cases early on the third day of the eruption, and a number of these passed through the ward Until Case 40 (the twenty first third day case) caused infection the apparent abrupt stoppage of the conveyance of infection by air was a matter of wonder to me, and could hardly be expected to be constant Yet it appears to hold good that it is unusual under the conditions in this ward for infection to be air borne, even from cases introduced early on the third day It is interesting to note the distances in the ward that the infection of chicken pox was aerially conveyed In all, 15 infections arose On two occasions the infection was conveyed the whole length of the ward, on three occasions about half the length of the ward, and in the remaining ten the distance was short The long and medium distance infections originated from four first day cases and a second day case and the latter accounted for one of the long distance infections

It must be understood that deductions as to the aerial conveyance of infection do not apply to any other conditions than those obtaining in this special ward for the results might be different were the beds closer to each other, the ventilation less good &c I have come to the conclusion that scarlet fever infection is not conveyed by air It has been following day and both were left in the ward As suggested in the former article, the more likely mode of infection was the inadvertent admission of a nurse to duty in the ward who was suffering from a septic finger, and who consequently was unable to wash her hands thoroughly It is well, however, to record one doubtful secondary infection in January, 1915 This was a case of diphtheria and whooping cough which developed a rash resembling scarlet fever, but I regarded the rash as being the result of the serum treatment for diphtheria. I admit the case may have been one of scarlet fever, and that I erred in my diagnosis, but the balance of the evidence was in accord with my conclusion

2 *Diphthera* —104 cases were treated. Of these, 51 were admitted during the first week of the disease and 53 at a later period. No secondary cases occurred

3 *Rubella* —41 cases of rubella were treated Of these, 32 were admitted on the first day of the disease, 6 on the second day, 2 on the fourth day, and 1 on or about the eighth day No secondary cases occurred

Several scarlet fever convalescents who had been exposed to rubella in other wards were admitted on the chance that they might develop the disease and so help to show if aerial conveyance would take place before the advent of the eruption None of these developed rubella Two of the nursing staff of the ward contracted the disease The first had the rash on April 10th, 1915 and she was on duty in the ward on April 8th The second developed the rash on April 13th, 1915, and she was on duty up to 8 A M on the 12th and not afterwards No infection arose from these contact exposures

On one occasion an opportunity arose of placing two first-day cases of rubella into the ward at the same time and advantage was taken of it On another occasion a first-day case and a second day case were placed in the ward at the same time

4 *Mumps* —23 cases of mumps were treated. Of these, 16 were admitted on the first day of the disease, 3 on the second day, 2 on the third day, 1 on the fourth day, and 1 on the fifth day On two separate occasions two first-day cases were admitted at the same time, but no infection resulted from these double introductions One infection of mumps arose and the infected patient occupied Bed 7 There were two possible sources of infection One patient admitted on the first day of the disease occupied Bed 2, and another admitted on the third day occupied Bed 9 Counting from the first day of exposure the incubation period in the former case would have been 35 days and the latter 15 days If infection was aerially conveyed I favour the former source I am doubtful, however, whether this infection may not have been due to some fault in the nursing technique

5 *Whooping cough* —75 cases were treated, including 2 infected in the ward Of these 34 were admitted during the first week of the disease, including the two infected in the ward, 19 were admitted in the second week and the remainder at a later period of the disease Five cases of infection occurred all of which are described in the original article Since July 15th 1913, there has been no whooping-cough infection, although 48 cases have been treated since that date

6 *Measles* —No case of measles was knowingly admitted to the ward, but 2 cases admitted with other diseases were incubating measles Both were productive of secondary cases, as described in the original article.

7 *Chicken-pox* —63 cases were treated, including 9 infected in the ward Of the 54 cases introduced, 3 were admitted on the first day of the disease, 4 on the second day, 31 on the third day, 7 on the fourth day, 2 on the fifth day, 3 on the sixth day, 1 on the seventh day, 2 on the eighth day, and 1 on the tenth day The 3 cases admitted on the first day of the disease all had fresh crops of lesions afterwards and 1 was an infecting case. This case had fresh crops of lesions until the fourth day and infected two patients The 4 cases admitted on the second day had fresh crops of lesions in two instances, one a copious crop Three of these infected one patient each, the 2 with fresh crops after admission and one of the others Of the 31 cases admitted on the third day 4 had a fresh crop of lesions next day 2 of which were copious crops, 1 of the cases with a copious crop was in Bed 6 and infected the occupant of Bed 8 The other three cases did not cause infection Of the remaining 27, 2 proved to be infecting cases and will be described below

A few of the earlier cases of chicken pox received "special nursing," which meant that the senior nurse on day or night duty was detailed off to look after the chicken pox case and was not allowed to touch any other patient except protected ones, and no other nurse was allowed to touch the chicken pox patient or anything connected with him

The 12th case was the last to receive "special nursing," therefore none of the undermentioned cases were so nursed.

19th case.—Bed 1 Third day, fresh vesicles on day of admission, but no fresh lesions in ward Eleven other cases in ward, 4 protected 7 unprotected. No infection

20th case —Bed 1 Tenth day, scabs only Six other cases in ward, 3 protected 3 unprotected No infection.

21st case —Bed 1 Third day, fresh vesicles on day of admission, but no fresh lesions in ward Eleven other cases in ward, 5 protected, 5 unprotected, 1 doubtful No infection

22nd case.—Bed 1 Third day, fresh vesicles on day of admission, but no fresh lesions in ward Eleven other cases in ward, 6 protected, 5 unprotected No infection

23rd case —Bed 1 Third day pustules but no fresh lesions in ward. Nine other cases in ward, 3 protected, 6 unprotected No infection

24th case —Bed 1 Third day, fresh vesicles on day of admission and fresh crop day after admission Nine other cases in ward, 5 protected, 4 unprotected No infection

25th case —Bed 1 Second day, vesicles few in number on admission and a fresh and copious crop day after admission Ten other cases in ward, 6 protected 4 unprotected Infected the occupant of Bed 11, who had been removed to another ward

26th case —Bed 1 Second day, vesicles but no fresh lesions in ward. Nine other cases in ward, 4 protected 5 unprotected. Infected the occupant of Bed 6, who had been transferred to another ward

27th case —Bed 1 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 3 protected, 7 unprotected, 1 doubtful No infection

28th case.—Bed 1 Fourth day, scabs only, no fresh lesions in ward Eight other cases in ward, 4 protected, 3 unprotected, 1 doubtful No infection

29th case —Bed 1 Third day, vesicles but no fresh lesions in ward Eight other cases in ward, 4 protected, 4 unprotected No infection

30th case —Bed 1 Third day, vesicles but no fresh lesions in ward Nine other cases in ward, 5 protected, 4 unprotected No infection

31st case —Bed 1 Third day, vesicles but no fresh lesions in ward. Nine other cases in ward, 5 protected 4 unprotected No infection

32nd case —Bed 1 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 7 protected, 4 unprotected No infection

33rd case —Bed 2 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 7 protected 4 unprotected No infection

34th case —Bed 1, Third day, pustules but no fresh lesions in ward Eleven other cases in ward, 5 protected 6 unprotected No infection

35th case.—Bed 1 Third day, vesicles but no fresh lesions in ward Eight other cases in ward, 4 protected, 4 unprotected. No infection

36th case —Bed 2 Third day, fresh vesicles on day of admission and a fresh and copious crop after admission Eight other cases in ward, 4 protected 4 unprotected No infection

37th case.—Bed 3 Third day, vesicles but no fresh lesions in ward Nine other cases in ward, 4 protected 5 unprotected No infection

38th case.—Bed 1 Third day, vesicles but no fresh lesions in ward. Ten other cases in ward, 2 protected 8 unprotected No infection

39th case —Bed 3 Third day vesicles but no fresh lesions in ward Eleven other cases in ward, 5 protected 6 unprotected No infection

40th case.—Bed 8 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward 5 protected 6 unprotected Infected the occupant of Bed 7 who had been transferred out of ward

41st case —Bed 3 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 3 protected 8 unprotected No infection

42nd case —Bed 10 Third day, vesicles but no fresh lesions in ward Eleven other patients in ward, 2 protected, 9 unprotected No infection.

43rd case —Bed 6 Sixth day, scabs but no fresh lesions in ward. Nine other cases in ward, 2 protected, 7 unprotected No infection.

44th case —Bed 8 Eighth day, scabs but no fresh lesions in ward Nine other cases in ward, 2 protected, 7 unprotected No infection

45th case.—Bed 5 Third day, vesicles but no fresh lesions in ward Eleven other cases in ward, 2 protected, 9 unprotected Infected the occupant of Bed 8 who was left in ward and in turn infected the occupants of Beds 6 and 9 No further infections

46th case.—Bed 7 Third day, vesicles fresh crop on day of admission but not in ward Eleven other cases in ward, 4 protected, 7 unprotected. No infection.

47th case.—Bed 10 Third day, vesicles fresh crop on day of admission but not in ward Eleven other cases in ward, 4 protected 7 unprotected No infection

48th case.—Bed 4 Third day, vesicles but no fresh lesions in ward Ten other cases in ward, 5 protected, 5 unprotected No infection

49th case —Bed 4 Eighth day, scabs but no fresh lesions in ward Eight other cases in ward, 5 protected, 3 unprotected No infection

50th case —Bed 9 Fourth day, vesicles but no fresh lesions in ward Six other cases in ward, 2 protected, 4 unprotected No infection

51st case —Bed 1 Third day, vesicles fresh crop on day of admission but not in ward Eight other cases in ward, 4 protected, 4 unprotected No infection

52nd case —Bed 6 Third day, vesicles, copious crop the day after admission to ward Eleven other cases in ward, 3 protected 7 unprotected 1 doubtful Infected occupant of Bed 8 who had been transferred to another ward

53rd case —Bed 1 Third day, vesicles fresh crop on day of admission but not in ward Nine other cases in ward, 2 protected, 4 unprotected 3 doubtful No infection

54th case —Bed 1 Third day, vesicles, fresh crop on day of admission but not in ward Nine other cases in ward, 2 protected, 4 unprotected, 3 doubtful No infection

As stated above, 3 out of the 31 third day cases each caused one infection The first (Case 40) was in Bed 8 and infected the occupant of Bed 7 The second (Case 45) was in Bed 5 and infected the occupant of Bed 8 The third (Case 52) was in Bed 6 and infected the occupant of Bed 8

Case 40 was the twenty first case of the series introduced on the third day of the eruption, and the first 19 of the series were each placed next to a protected case or between two protected cases Case 39 was placed between a protected and an unprotected case, and Case 40 between two unprotected cases, and although 39 failed to infect, 40 did The bringing nearer to infection of the unprotected cases may reasonably be considered to add to the danger This course was persisted in until the ward closed, with the result that 6 *cases of* chicken pox had each been placed between unprotected cases, 5 next unprotected cases on one side only and 1 between an unprotected and a doubtfully protected case The only infection was the one recorded above

The next third day infecting case (Case 45) I cannot satisfactorily account for This patient, who occupied Bed 5 was placed between two unprotected cases and did not infect either of them but did infect the occupant of Bed 8 directly on the opposite side of the ward It is to be noted that the occupant of Bed 6 escaped infection from Case 45 he was left in the ward as well as the occupant of Bed 8 from whom he contracted chicken pox Case 45 was not a patient from whom to expect infection for the total number of lesions was quite moderate and there were no fresh lesions on the day of admission or later the second crop having occurred on the day prior to admission to the ward It may be that the occupant of Bed 8 was a peculiarly susceptible child, and that the occupant of Bed 6 could withstand infection to some extent, but responded to a more powerful infection On the whole, however, I think that the occupant of Bed 8 was probably infected by indirect contact due to some error in the nursing technique I am the more disposed to take this view, knowing the difficulty of maintaining the nursing at the highest level at that time

The last third day infecting case (Case 52) might also be attributed to faulty technique, but I do not feel satisfied that such an explanation is justifiable, though the possibility must be admitted This patient was in Bed 6 and infected the occupant of Bed 8, not quite directly opposite, but failed to infect an unprotected child in the bed next to him Case 52 had a large crop of fresh lesions on the day following admission to the ward, which may very well account for the infection On the other hand, it must be remembered that three other third day cases had fresh crops of lesions on the day following admission (one of them a large crop), without causing infection Up to, and including, Case 31, only one third day case of chicken pox was introduced into the ward at the same time It was then thought desirable to introduce two third day cases at the same time if they could be procured This was done with Cases 32 and 33, and they were placed in Beds 1 and 2, and the same course was adopted with Cases 35 and 36, also in Beds 1 and 2 Finally it was done with Cases 46 and 47, who were put into Beds 7 and 10 In this instance two unprotected cases lay between 46 and 47, and another unprotected patient next to 47 on his other side No infection arose from these three double exposures

Comparatively early in the investigation, having introduced a number of third day cases without infection having arisen, I thought that the second day case, early in the series, which had produced infection, might have been exceptional, or possibly due to some error in technique Therefore, I introduced Cases 25 and 26 on the second day of the eruption However, both of these caused infection I subsequently commenced introducing cases early on the third day of the eruption, and a number of these passed through the ward Until Case 40 (the twenty first third day case) caused infection the apparent abrupt stoppage of the conveyance of infection by air was a matter of wonder to me, and could hardly be expected to be constant Yet it appears to hold good that it is unusual under the conditions in this ward for infection to be air borne, even from cases introduced early on the third day It is interesting to note the distances in the ward that the infection of chicken pox was aerially conveyed In all, 15 infections arose On two occasions the infection was conveyed the whole length of the ward, on three occasions about half the length of the ward, and in the remaining ten the distance was short The long and medium distance infections originated from four first day cases and a second day case and the latter accounted for one of the long distance infections

It must be understood that deductions as to the aerial conveyance of infection do not apply to any other conditions than those obtaining in this special ward for the results might be different were the beds closer to each other, the ventilation less good, &c I have come to the conclusion that scarlet fever infection is not conveyed by air It has been held for many years that the infection of diphtheria is not air borne, and the evidence in this ward only makes it clearer that this opinion is correct

I am disposed to regard the evidence as strong against the conveyance of rubella infection by air A considerable number of the cases of rubella introduced into the ward during the winter of 1914–1915 came from two scarlet fever wards into which the infection had come from outside the hospital, and in these two wards the infection persisted for many weeks although new patients were not admitted Such persistence of infection in this disease is uncommon, and therefore indicated unusual activity

I was surprised when an infection arose from mumps (if the infection was aerially conveyed), and I still incline to the view that this disease is probably not air borne

The last infection of whooping cough occurred on July 15th, 1913, although since that time 48 cases have been treated in the ward Nevertheless I confess I am still in doubt as to whether this disease may be occasionally air borne or not, Taking into consideration the propelling power of the cough, I feel that longer experience is necessary before a reliable conclusion can be reached

I am quite satisfied that chicken pox infection is air borne early in the disease, but it is difficult to determine the exact time it ceases to be so It may uncommonly be conveyed by air on the third day, but apparently not afterwards

A Note on Contact Infection in Chicken pox

Although it is safe to treat chicken pox at certain stages of the disease in this special ward with all its precautions against direct and indirect contact infection, it does not follow that it would be safe to treat it in a similar, or even scabbing, stage in an ordinary ward where no such precautions were taken It is commonly held that chicken pox remains infectious until the last scab has separated from the patient s skin For many years I have been unable to accept that view, and I have often placed patients who were approaching the completion of the scabbing stage into wards amongst children who were not suffering from chicken pox With the intention of working this subject out systematically I decided towards the end of 1914 to introduce cases of scarlet fever and chicken pox into a small boys scarlet fever ward, but not to guard against contact infection in any way I purposely chose a ward in which the patients were young, and the ages of the unprotected exposed to the cases of chicken pox were—one year, 1, two years, 5, three years, 8, four years, 13, five years, 12 six years, 15, seven years, 2, and eight years, 5 As it was necessary that the patient introduced should be a male suffering from both scarlet fever and chicken pox, and that no other patients should be admitted to the ward while each test was in progress &c the work was necessarily slow In all, 7 patients suffering from both diseases passed through the ward 1 being introduced on the sixteenth day of chicken pox, 1 on the twelfth day 1 on the eleventh day, 1 on the tenth day 2 on the ninth day and 1 on the eighth day Only one case was introduced at a time, and was kept in the ward until all the scabs had separated, or longer while no patient was discharged until more than 22 days had elapsed after the first exposure, many being kept much longer No infection arose from any of these cases The ward in which this work was done accommodated 20 patients

1st case —Sixteenth day of chicken pox, numer scabs Nineteen other patients in ward 12 protect 5 unprotected, 2 doubtful No infection

2nd case.—Eleventh day, a few scabs Eight other cases in ward 12 protected, 5 unprotected, 1 doub No infection

3rd case.—Tenth day, moderate number of scabs Ni teen other cases in ward 5 protected, 12 unprotect 2 doubtful No infection

4th case.—Ninth day, scabs fairly numerous Eighte other cases in ward 9 protected, 7 unprotected 2 doubtf No infection

5th case —Twelfth day, scabs fairly numerous Ni teen other cases in ward 10 protected, 9 unprotected. infection

6th case —Ninth day, scabs very numerous Eighte other cases in ward 9 protected, 8 unprotected, 1 doubtf No infection

7th case.—Eighth day, moderate number of sca Nineteen other cases in ward 4 protected, 15 unprotec No infection.

Although only seven cases of chicken pox in t scabbing stage have passed through the ward yet, it is sufficient to show that I was justified my disbelief of the generally accepted view Wh it is interesting that the last case was introdu as early as the eighth day, yet it will probably t a considerable time to discover the exact day of t disease on which the chicken pox patient ceases be a danger to those with whom he comes contact Nevertheless, enough has been done lead to economy in the provision of isolat accommodation for this disease in hospitals, a to show that it is needless to keep the chicken p patient separate from others for so long as generally supposed necessary

North Eastern Hospital Tottenham N

THE UREA CONTENT OF THE CEREBR SPINAL FLUID

WITH SPECIAL REFERENCE TO THE DIAGNOSIS OF URÆMIA

By R G CANTI, M A, M B CANTAB,
DEMONSTRATOR OF PATHOLOGY ST BARTHOLOMEW'S HOSPITAL
PATHOLOGIST TO THE ALEXANDRA HOSPITAL, QUEEN SQUARE

IN recent years a considerable amount of wo has been carried out, chiefly by French observe on the urea content of the cerebro spinal flu Mestrezat, who has collected the data of Jav Dirksen, Widal, Froin, Froment, and many othe and who has made many additional observatio has come to the following conclusions 1 T normal physiological urea content of the cereb spinal fluid is 0 006 per cent 2 Cases of re impermeability to urea without uræmia may sh up to 0 1 per cent of urea and occasiona individuals may have a larger quantity witho showing clinical signs 3 Cases of clinical uræ in which no other disease is present (i e ' p uræmia) have been found to have 0 093 0 634 per cent, and of these cases those w readings below 0 3 per cent are curable and th with readings above 0 3 per cent are fatal (Molli and Froment, to whom the terms 'pure a "associated' are attributable, choose 0 4 per ce as the dividing line) 4 Cases of clinical uræm in which some other disease is present (i "associated uræmia) have been found to sh 0 1 to 0 764 per cent of urea 5 The content urea present in the cerebro spinal fluid wheth it be normal or raised, is approximately the sa as in the blood

In determining the figures given below the following methods of collection and determination have been adopted —

1 *Collection of cerebro spinal fluid* —Ante mortem Lumbar puncture has invariably been employed. Post mortem Lumbar puncture has occasionally been employed, but often sufficient fluid has only been obtained with difficulty It has been found that a greater amount could be obtained by one of the following methods (*a*) Puncture of the occipito atlantoid ligament, with or without a skin incision, and drainage of the cerebro spinal fluid from the sub cerebellar cisterna This method of gaining entrance has been described by Dixon and Halliburton, and has been used by Gordon in experiments on monkeys (*b*) When the brain has been removed a No 6 gum elastic catheter is introduced down the spinal canal in front of the cord, and the fluid withdrawn by means of a syringe

2 *Method of determination* —The hypobromite method has been employed 5 c c of the cerebro spinal fluid, centrifugalised if turbid, was mixed with the sodium hypobromite solution (25 c c of 40 per cent potassium hydrate solution in which an ampoule containing 2·2 c.c of bromine had been broken and the solution allowed to cool) and the gas given off was measured as percentages of urea The apparatus was essentially that of a Gerrard s ureometer except that the measuring tube was much narrower (about 12 mm) in order that 0·01 per cent could be read with accuracy Care was taken that the temperature in the mixing bottle was the same at the beginning and end of each experiment, but no allowance was made for small variations caused by alterations in temperature and pressure between separate experiments Chemically the reaction is complicated and the quantity of gas given off is influenced by nitrogenous substances other than urea In blood serum these substances exist in large amount but in the cerebro spinal fluid they are to a great extent absent

Most of the estimations were performed post mortem In nine cases they were performed both post mortem and ante mortem and it was found that the difference between them varied from 0·01 to 0·10 per cent the average post mortem reading being 0·06 higher The results may be collected into the following six groups

Group A *Normal Urea Content*

Owing to the difficulty of obtaining cerebro spinal fluid from perfectly normal individuals no figures have been obtained to determine the urea percentage Seven cases, however being all the cases examined ante mortem, in which there was reason to believe that the kidneys were natural or not materially damaged, show figures which should be comparable with the normal The amounts of urea vary from 0·02 to 0·05 per cent

Group B (vide *Table I*)

The urea content in cases clinically diagnosed as or suspected of [illegible] 0·20 per cent [illegible] post mortem This latter [illegible] average [illegible]

Of the 20 cases 19 were diagnosed as uræmia a [illegible] (No 2) was a suspected case Of those diagnosed 13 correspond to the pure uræmia of [illegible] and have urea readings between 0·23 and 0·83 per cent 6 had some com[illegible] and correspond to the associated [illegible] group In the [illegible] the percentage of urea varied from 0·2[illegible] to 0·51 per cent The age incidence [illegible] the majority of the patients was that of the first half of life No 114 is the only case of acute nephritis examined The patient died on the twenty ninth day after the commencement of scarlet fever As regards the blood pressure, the average of all the readings obtainable (occasionally more than once from the same patient) was 160 mm of mercury, and the average weight of the heart in adults was 15 oz.

TABLE I

No of case	Sex and age	Associated disease if any	Blood pressure (mm Hg)	Albumin in urine (per cent)	Weight of heart (ounces)	Urea percentage—	
						Ante mortem	Post mortem
1	M 39	—	230 150	0·3	16	—	0·40

105	M 33	Tuberculous kidneys		++	12	0·39	0·40
109	F 40	Syphilitic endarteritis	—	++	24	—	0·35
114	M 5	—	—	0·25	?	—	0·41

In the majority of the 19 cases there was a large quantity of albumin present in the urine The remaining case, No 2, was that of a man of old age who had a high blood pressure, a hypertrophied heart and but little albumin in the urine Post-mortem examination revealed a hæmorrhage in the right optic thalamus which was undoubtedly the direct cause of death

Group C (vide *Table II*)

The urea content in cases clinically diagnosed as or suspected of being uræmia in which the reading was below 0·10 or 0·15 per cent. post mortem

Firstly those in which the diagnosis was entirely mistaken—viz. Nos 35 and 92

Secondly, cases of chronic nephritis

(*a*) *Non fatal cases* (Nos. 86 89 and 98) —The patients suffered from various combinations of the following signs and symptoms headache vomiting, dyspnœa œdema diminution of urine, albuminuria, and albuminuric retinitis Twitchings, fits, drowsiness and coma were absent They all three were discharged from hospital in an improved condition, and one case, who had 0·43 per cent of albumin in the urine and marked albuminuric retinitis, was known to have remained in fairly good health for at least six months

(*b*) *Fatal cases* (Nos 33 52, and 71) —Coma was the prominent sign in the first, and fits were present in the remaining two In all three cases cerebral lesions were found on post mortem examination

CASE 71 —The patient, a woman, aged 22, had suffered from headache and vomiting at intervals for 18 months, shortly before admission she noticed swelling of the ankles and face On examination no œdema was found, she had headache vomiting, albuminuric retinitis, and much albumin in the urine which was diminished in quantity She improved under treatment, and the urine increased to physiological amounts. After a month she was able to get up She then developed a left-side facial palsy, with pain and deafness in that ear One evening shortly after she had gone to bed she was found with twitching of the arms and face in an unconscious condition, from which she never completely recovered On post-mortem examination a ruptured aneurysm was found on the anterior communicating artery giving rise to a subdural hæmorrhage over the right hemisphere

Thirdly, cases of cardio vascular disease (arterio capillary fibrosis of Gull and Sutton)—viz, Nos 90, 95, and 97 With regard to the diagnosis of uræmia in cases of this kind and in those with various forms of nephritis proper, a considerable amount of work has been performed at St Bartholomew's Hospital, but has not yet been published The inquiries deal with the clinical diagnosis, the histology of the kidneys, the tests for renal insufficiency, the condition of the fundus oculi, and the variations of the carbon dioxide content of the alveolar air, and though it is beyond the province of this paper to enter into details, yet it may be said that there is a general convergence of opinion that the two conditions are widely different, the one which we are now considering being due to the failing action of the heart beaten by its task Of the cases examined all responded to means taken to ensure more efficient action of the heart and were discharged in a greatly improved condition The maximum blood pressure which these patients show, when not suffering from cardiac inefficiency, is seen to be over 200 mm of mercury

TABLE II

CASE 95 —The patient a man aged 61, had been suffering with headaches for the past few years which were throbbing in character He had had no giddiness nocturnal micturi tion, or shortness of breath On admission on Oct 25th 1914 the heart was hypertrophied but with no valvular disease the temporal and radial arteries were tortuous, the blood pressure was 260 mm of mercury The urine was diminished and contained 0 025 per cent of albumin On Nov 13th his blood pressure was 220 mm of mercury and on the 17th he began to be drowsy On the 18th he was given a hot air bath phlebotomy was performed 8 ounces of blood were withdrawn, and 1¼ pints of physiological saline sol injected and he was fed through the nose. On the 19th he was almost unconscious, the blood pressure was found to be 135 mm of mercury, and lumbar puncture was performed and the urea estimated and found to be 0 05 per cent. He was then given 0·0005 grm of digitalin, and ordered a mixture of strychnine and digitalis The next morning he was somewhat better though still semi conscious but in the afternoon he roused himself suddenly and asked for a cup of tea. From that day his blood pressure gradually rose and he began to get better He was discharged about a fortnight later in a much improved condition with a blood pressure of 190 mm of mercury

Table III shows a comparison of the more important signs and symptoms usually found in the two groups of cases In Column 1 are placed the conditions some or all of which are found in cases clinically diagnosed as being uræmic in which a high urea content is found in the cerebro spinal fluid In Column 2 are the corresponding conditions found in cases of cardio vascular disease in which the patient is suffering from high blood pressure symptoms, but otherwise is in a fairly good state of health Column 2A shows the alteration in signs which occur in various degrees of heart failure in the course of cardio vascular disease Failure of the left side of the heart is followed by fall in blood pressure, diminution in urine dyspnœa, cyanosis, delirium and coma, and failure of the right side, should it supervene by œdema and albumin in the urine A comparison of the signs and symptoms in Columns 1 and 2A clearly demonstrates how one condition may be mistaken for the other, and at the same time shows the value of a urea estimation for purposes of differential diagnosis

Urea content in cases not clinically diagnosed as or suspected of being uræmia in which the reading was above 0 10 per cent. ante mortem or 0 16 per cent post mortem

It is unnecessary to enter into details of these cases, which would unduly lengthen this paper It will suffice to say that the condition of the patients was such that any signs of clinical uræmia present were either altogether masked or attributed, rightly or wrongly, to some other cause

Group E

Urea content in cases not clinically diagnosed as or suspected of being uræmia in which the urea content was below 0·10 per cent ante mortem or 0·16 per cent post mortem

This series consists of 55 observations on a large variety of cases, which it is unnecessary to enumerate, and demonstrates the absence of urea in the cerebro spinal fluid in the majority of diseases, even as a terminal event

Group F

This group contains the cases of diabetes examined (ten in number) They show a urea content which varies from 0·07 to 0·34 per cent, and they have been placed apart as the reading obtained by the hypobromite method is erroneous This is shown by the following experiment A solution of urea in water was estimated for urea Dextrose was added to a fresh portion of the same solution and the estimation performed again The second reading was considerably higher than the first, showing that dextrose is at least one of the substances which may cause a high reading in cases of diabetes

From the foregoing observations it appears that —

1 The normal physiological urea content of the cerebro spinal fluid, as measured by the hypobromite method is below 0·05 per cent

2 Cases clinically diagnosed as uræmia fall under two headings (*a*) Those which have a high urea content All were fatal cases Thirteen were uncomplicated renal disease Six were complicated with disease other than renal The remaining one died from cerebral hæmorrhage (*b*) Those which have a low urea content In two the diagnosis was altogether mistaken In three there was chronic parenchymatous nephritis They had œdema or vomiting or both, but no fits were [illegible] They recovered and were discharged in an improved condition Three more suffered with chronic parenchymatous nephritis Fits were [illegible] in two They all died and were found to have cerebral lesions Three had cardio vascular [illegible] and cardiac failure was present They were discharged in an improved condition

3 Cases not clinically diagnosed as uræmia fall also under two headings (*a*) Those with a high urea content They were all cases complicated by disease other than renal, and any signs suggestive of uræmia which may have been present were either masked or attributed to some other cause (*b*) Those with a low urea content

The term "uræmia" is used to group together some or all of a set of signs and symptoms occasionally found in pathological conditions of the kidney It has long been observed that there existed differences between individual cases, which divided "uræmia" into certain types, and it has been proved that excess of urea in the system is not of itself the cause of "uræmia" The term, therefore, is admittedly vague and fallacious, but it seems necessary to retain it, at any rate for the majority of such conditions, as it conveys to the mind a definite group of clinical entities

The number of cases examined in this paper is too small for statistical purposes, but certain points have been observed which give a clue to the differentiation and a clearer prognosis of the various conditions diagnosed as uræmia

Firstly, of the cases so diagnosed which die, the majority are found to have a greatly increased quantity of urea in the cerebro spinal fluid, usually about ten times, and occasionally more than twenty times, the normal amount For these the term "true uræmia" is suggested Sometimes an "associated" disease is present, but more often the condition is "pure," in which case the quantity of urea present tends to be somewhat higher Every case in which a greatly increased quantity of urea has been found in the cerebro spinal fluid has proved fatal within a short period

Secondly, a few cases of large or small white kidney have been diagnosed as suffering from uræmia, and little or no excess of urea has been found in the cerebro spinal fluid Of this group, those which recovered had no fits, and those which died were found to have cerebral lesions

Thirdly, a certain number of cases of cardio vascular disease (arterio capillary fibrosis) are diagnosed as uræmia It has been shown that the signs and symptoms suggesting such a diagnosis can be due to cardiac failure, that the patients respond to treatment directed towards restoring the efficiency of the heart, and tolerate badly treatment directed towards overcoming a toxic condition of the blood and tissues, and that there is no excess of urea in the cerebro spinal fluid For these cases it seems imperative that the term "uræmia" should no longer be employed As long ago as 1872 Sir William Gull was contending with the same fallacy when he spoke thus at a clinical lecture at Guy's Hospital "At the present time there is a dominant idea in respect of chronic Bright's disease with contracted kidney, that the various functional disorders and lesions which occur in its course are chiefly if not entirely connected with a *materies morbi* in the blood to which such disorders and lesions are chiefly referable The theory that all or most of the symptoms in chronic Bright's disease are due to uræmia is frequently fraught with dangerous and destructive effects in practice I call vividly to mind the unhappy results of treatment so directed

The writer is indebted to the members of the staff and to his colleagues in the Pathological Department of St Bartholomew's Hospital for their kind advice and assistance in enabling him to collect

notes and material, and especially to Dr Gordon, who originally suggested the research

The expenses of this work were in part defrayed by a grant from the Government Grant Committee of the Royal Society

PROPHYLACTIC VACCINATION AGAINST HAY FEVER

BY B P SORMANI,

LECTURER ON SEROLOGY AT THE UNIVERSITY OF AMSTERDAM

(From the Laboratory of the Onze Lieve Vrouwe Gasthuis)

IN the hay fever season of last year I had an opportunity of observing the results of vaccination or active immunisation with extract of pollen in 48 cases These patients included three whose cases I dealt with in a previous paper[1]

Noon,[2] who, like Dunbar, considered hay fever a toxic disease, treated the patients before the hay fever season arrived with the toxin itself by applying an extract of the pollen Though this is a prophylactic vaccination he yet applied the treatment according to Sir Almroth Wright's rules of therapeutic vaccination He fixed the quantity of each dose in accordance with the resistance of the patient against the toxin, measuring this quantitatively by the ophthalmo reaction of Elliotson and proposed to begin with a dose of one third of the number of units representing the resistance The succeeding dosage was then settled in accordance with the altered resistance

After Noon's death Freeman, who continued his work, prepared the extract by a method similar to Noon's—viz, freezing and thawing 40 or 50 times the pollen suspended in water Then the fluid, which is slightly green, is centrifuged, and sterilised for ten minutes at 100° C The slight green colour appears about the 30th freezing, as Freeman wrote to me In this way an extract is made of the whole pollen growth of one year, and is used for diagnosis and treatment before the hay fever season begins Freeman[3] commences his treatment generally in October of the preceding year and continues it as long as possible

The treatment here described I began to apply during the winter of 1913–14 in the three cases already recorded The results were very favourable and encouraged me to proceed on the same lines, which were in some respects different from the methods of Freeman Let me explain these differences

First, I rejected Noon's dosage method As the treatment is a prophylactic one I did not see why it should be necessary to regulate the dosage as if the disease existed already Wright's opsono therapeutic rules were made for existing diseases and they keep in view the possibility that an overdose would for a short time neutralise too many antibodies, in consequence of which the infection might progress undisturbedly Wright himself, however, gives up this method if there is any question of a prophylactic treatment I have only to recall his antityphoid inoculation, for which he prescribes the injection of 1000 and 2000 millions of typhoid bacilli with an interval of from 8 to 10 days Undoubtedly the first dose might cause a negative phase lasting for more than 10 days, and consequently the second dose would become dangerous if this vaccination was not a prophylactic but a therapeutic measure The prophylactic vaccination for hay fever may be absolutely compared to this antityphoid vaccination, and I think that dosage in cases like this is only to be determined by what the patient is able to support without any trouble In determining the first dose of 1000 millions of typhoid bacilli Wright probably only considered how many typhoid bacilli a normal man could stand without suffering any serious reaction

I took this into consideration when regulating the dosage of pollen extract, and I found that everyone can support 10 U P as an initial dose without any considerable trouble When, however, more was given for an initial dose the local reaction was very troublesome owing to the extension of the swelling that followed, sometimes being accompanied by itching over the whole body and sometimes by urticaria This at the same time condemns Noon's method of dosage For instance, if the resistance before the treatment is found to be 1500 U P, I should not dare to give 500 U P as an initial dose Moreover, there was another reason why I refused to follow Noon and Freeman in their dosage, a reason which may be only of theoretical interest, however, because I have never tried to prove it After treating a patient for hay fever for some weeks or even months we have not only inoculated toxin, but also a great number of other kinds of albumin found in pollen which have nothing to do with the poisonous fraction If we determine the resistance by ophthalmo reaction we must agree that allergy may be produced for those other albumins, and who can prove that in this way the resultant figure has not been influenced? I, at any rate, could not accept it as a perfect test That a hypersensibility for the pollen extract can be originated is well proved by the fact that now and then urticaria is observed during the treatment There is no reason why this should be caused only by the toxic albumin which causes hay fever

Accordingly in January February, or March I began the treatment by administering a dose of 10 U P, increasing the amount every week as far as possible in each case Generally I proceeded up to 1000 U P, but when the patient showed symptoms of an overdose the increase was very slow or not at all

I altered also the preparation of the extract I ground the pollen by rubbing it with sterile sand and made the extract with distilled water This extract was not boiled, but was sterilised by adding one tenth of its volume of 5 per cent carbol solution, after which salt was added up to 0 85 per cent Of course, carbolic acid was not added to the extract which had to serve for the ophthalmo reaction, but it was boiled for 10 minutes, as Freeman does

Finally, it is a well known fact that the solution of pollen toxin soon loses its antigen power, at least partly Noon and Freeman were of opinion that they might take for granted that the toxin standard did not diminish, founding their opinion on the fact that the ophthalmo reaction was obtained as perfectly with old as with new extract. Nevertheless, I think it is better to use only fresh vaccine for inoculations which is no trouble worth mentioning, as the vaccines made in the simple way described were not less effective than those prepared on Freeman's method.

[2] THE LANCET June 10th 1911 p 1572. References were given in the paper already mentioned

[3] THE LANCET Sep 16th 1911 p 814 April 25th 1914 p 1178

In each case I first determine the ophthalmo reaction. In most of my patients I found a resistance of 500 U P. The reaction is not sharp, at all events, in my opinion, not such as to serve as a guide to treatment. Notwithstanding this I consider it to be of the highest importance to make an examination in the beginning for diagnostic purposes, for in this way I proved that two cases suspected to be hay fever were something else. If in such a case we inoculate against hay fever without previous diagnosis wrong statistics as to the effect of this treatment are obtained. All other patients showed a clear positive reaction. The lowest resistance which I found was 5 U.P., the highest 5000 U P. Almost all these had been treated in every possible way: the nose had been treated with cautery or scalpel, they had been injected with pollantin and graminol, rhioculin had been used, chalk therapy was applied but all without any success.

Before relating the results of the treatment it may be observed that the past hay fever season, in the opinion of patients not treated prophylactically, was very severe and even more unfavourable than the preceding three years. I saw some very bad cases. The treatment I applied in 1915 was as follows: The initial dosage was always 10 U P. A little reddening and swelling were observed at the place of injection. The dose was increased every week generally as follows: 20, 30, 40, 50, 70, 90 and then beyond 100 more rapidly—thus 150, 200, 300, 400, 500, &c. Various circumstances prevented me from beginning before February, but in a few cases it might have been better to have begun earlier. I believe so, but it is rather an unfounded opinion, for a few patients who began in April, and even in May, were perfectly cured.

In the matter of dosage I had proposed to myself to go when possible up to a final dose of 1000 U P, which appeared to me a very high dose. And so it proved to be, for some patients even it was too high as shown by the resulting symptoms. It also appears that it is often unnecessary to proceed to such a high dose as some patients were well cured with a much lower final dose than 1000 U P.

I think it is desirable to proceed to higher dosage only if during the preceding immunisation nothing has appeared leading to a suspicion of hypersensibility such as general itching or symptoms of an attack of hay fever (irritation and swelling in the eyes, a slight attack of asthma for a short time or anything of that kind). Now and then these symptoms appear and of course are very unpleasant, but I think they are rather difficult to [illegible]. They are not exclusively to be attributed to overdose, for in some cases all appeared even with very small doses. However I am bound to [illegible] of the patients or their physicians [illegible] the symptoms [illegible] disagreeable [illegible] treatment. Moreover I may point out [illegible] I once or twice discovered slight by- [illegible] prophylactically [illegible] I do no [illegible] know to what cause this difference is to be attributed. That these by-symptoms are not prevented by Freeman's method of dosage I learned from a letter from my colleague L—— at Z——, in which he cited the case of a patient, who, in 1914, after the first injection of Freeman's vaccine (pollacin), measured on Freeman's method, had a violent attack of asthma in the night.

At the end of May I stopped the treatment, but I always asked the patients to return at once if any symptom of hay fever appeared. If a patient returned I did not then give so high a dose as in May, but decreased it to 50 or 100 U P for fear of a negative phase. Soon this fear proved not unfounded, for a patient who during the hay fever season had been given once 1000 U.P. wrote to me and described what were undoubtedly attacks.

In the hay fever season itself I had the opportunity of studying the results of therapeutic inoculations in non prophylactically treated patients. In these cases I began with from 5 to 10 U.P., sometimes making no increase at all and sometimes increasing when it seemed necessary, but then only to 25 or 50. The experience in one case proves that 50 U P cannot be given in the hay fever season to non prophylactically inoculated patients without bad consequences. The patient who was already completely cured by from 5 to 25 U.P., had a violent attack after increasing the dose to 50 U.P. I consider these facts to be good ground for believing in the existence of a negative phase, although several vaccino therapeutists doubt this because they have never, or clinically not always clearly, observed it in prophylactic antityphoid vaccinations.

The results of the cases treated during 1915, either by myself or by other doctors after correspondence with me, are as follows:—

1 Of 14 patients I treated prophylactically, 6 were completely cured, 6 felt very little of their former sufferings, whilst 2 considered they had received but little benefit from the treatment.

2 Of 12 patients I treated only phylactically 4 were completely cured, whilst 3 felt more or less relief, and 5 felt no relief at all.

3 Of 19 patients treated prophylactically by other physicians, all found much relief (it is rather difficult to decide from their letters how much or how little), whilst of 3 treated therapeutically all found relief.

This brief summary shows as well as possible the experiences of myself and others. It must be pointed out that it is exceedingly difficult to express in a few words the result of the treatment. Some patients, for instance, are highly enthusiastic about the effect although I had to note slight attacks from which they suffered after a short railway trip. Very often those slight attacks consist only of irritation in the eyes or slight catarrh which anyone who does not suffer from hay fever would scarcely have noticed but which in the patient concerned take the place of previously unbearable conjunctivitis, asthma and catarrh of the whole respiratory tract. By these remarks I desire to show that I have been anxious to err if anything rather on the side of pessimism in compiling and summarising the results. Consequently there is good reason for considerable satisfaction.

Finally I would advise a slow increase of dosage, further to begin as early as possible, and using every time a fresh vaccine to give only so much as will produce a minimum local reaction. The local reddening should not exceed 5 cm. across

Moreover, the patient should be asked repeatedly if he has general itching or slight urticaria, or irritation in the eyes Until we find an animal suitable for experimentation, this therapy will only advance very slowly The experiences of the method already gained are, however, better than the results of a great many older methods of treatment, and this in itself may be regarded as an acquisition In this paper I have endeavoured to prove that it is possible to simplify the method of Noon and Freeman so far as to enable the practitioner to apply the vaccine in these cases without fear of obtaining less good results

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

◆

A CASE OF FEBRIS COLOMBENSIS

BY G A LURIE, M D CHICAGO,
ATTACHED TO THE AMERICAN RED CROSS SANITARY COMMISSION IN SERBIA

IT may be of interest to place on record a case of febris colombensis I have recently observed in Serbia. On this fever, which was first described by Castellani in Ceylon in 1905, there is very little literature, the only papers on the subject known to me, apart from Castellani's publications, being one by Fulle and one by Spaar This fever, as noted by Castellani, sometimes resembles typhoid or paratyphoid, at other times it is more like Malta fever with several relapses The onset is in most cases slow and gradual, but at times it may be quite abrupt, the general condition of the patient is usually rather severely affected, and a true typhoid state may develop, but very mild cases may also be met with No roseola or other rashes have been noted, and the spleen is seldom palpable, there may be constipation or diarrhœa No case so far has ended fatally, but the general condition may be very severe *As regards complications and sequelæ, cystitis has been noted and osteo* periostitis

The patient, an Austrian, had been prisoner in Serbia since December, 1914 There was nothing worth noting in his past medical history He never had been in the tropics At the end of June, 1915 while in Skoplje (Uskub) he began feeling tired and feverish and was seen several times by me, first as an out-patient at the American Clinique and afterwards at the Second Reserve Hospital The fever was of a subcontinuous type the temperature seldom exceeding 103° F, and it lasted for five weeks, terminating by lysis The general condition of the patient never was very severe No roseola, no enlargement of the spleen, no complication of any kind

The bacteriological examination of the case was carried out with the kind assistance of Mr D de Silva. The blood was examined for agglutination for typhoid paratyphoid A and paratyphoid B, and Malta fever four times—three times during the course of the fever and once two weeks after the fever was over, always with negative results, while it agglutinated B colombensis, Ceylon strain (cultures kindly supplied by Professor Aldo Castellani) in dilutions of 1/40 1/80 and occasionally 1/160 No hæmocultures were carried out, but the stools collected in a large sterile Petri dish were examined bacteriologically in the usual way by plating &c B typhosus and paratyphosus A and B were absent while 4 colonies out of 26 investigated turned out to be bacillus colombensis the others being coli and coli like bacilli

The strain isolated from this patient is identical to the Ceylon strain and corresponds in every particular to the description given by Castellani It is a motile bacterium, Gram negative, does not liquefy either gelatin or serum On agar the growth may be typhoid like, or the germ may grow more abundantly than true typhoid The germ grows well in milk, rendering the medium acid at first alkaline later, and often bleaching it, at times the medium may become permanently acid As regards sugar *reactions, as stated* by Castellani and Spaar *there is no production of gas in* saccharose, raffinose adonite, inulin, inosite, amygdaline, or erythrite while there is formation of gas in dulcite, mannite glucose, maltose, dextrin (very slight), arabinose sorbite, glycerine, isodulcite, galactose, levulose, and salicin

It is interesting *to note the action on* lactose I *can completely confirm* the previous observation *made* by Castellani and Spaar, that the same strain may at times produce a little gas in lactose and at other times none, while the colonies of the germ on MacConkey bilesalt lactose agar are always white, never red

The peculiar inconstant *action of the germ on lactose renders its classification difficult* When it does not ferment lactose, as is often the case when freshly isolated, its cultural characters are very similar to B paratyphosus B, when it produces gas in lactose it is more closely related to B coli The germ, however, as demonstrated by Castellani Fulle, and Spaar is never agglutinated by either paratyphoid B or A serum, nor by any of the many *coli sera tried*

There can, *in my opinion, be no doubt* that the case I have described is one *of febris colombensis* as *Castellani's bacillus* colombensis (1905) was isolated from the stools and the blood agglutinated strongly both the strains isolated from the patient and the original Ceylon strain, while it did not present any agglutination for the typhoid, paratyphoid A and B bacilli, and Malta fever micrococcus Moreover, the agglutination slowly and *gradually decreased after the fever was over* *This case shows that febris colombensis is not limited to the tropics, but is found also in temperate* climates and must be regarded as a cosmopolitan disease

CASE OF INTRACRANIAL HÆMORRHAGE WITHOUT SYMPTOMS OF COMPRESSION

BY P W LAM, M B, CH B EDIN,
AND
ED LAW, M B, CH B EDIN,
RESIDENT SURGEONS DISTRICT HOSPITAL WEST BROMWICH

IT is a matter of common knowledge that cases of head injury admitted to the casualty department of a general hospital often present difficulties in diagnosis, and the following case illustrates one of these difficulties

The patient a man aged 32 whilst cycling down an incline on Jan 1st 1916 collided with a car He was thrown off his bicycle and his head knocked against a post on the side of the road On admission at 9 15 A M an hour after the accident, he was [illegible] scious but could be partially aroused by strong stimuli The pulse was 76 per minute respirations 18 and temperature 99° F The pupils were equal in [illegible] and dilated and reacted sluggishly to light, the conjunctival reflex was present The skin was cold and pale There was a wound on the right side of the scalp extending from before backwards for about 1 inch and situated over the right parietal eminence From this a small quantity of blood was oozing On probing, the wound was found to be quite superficial and no bare bone could be detected No other injuries were present except a bruise over the upper part of the left arm Two hours after admission he vomited a large quantity of coffee coloured fluid and passed urine in bed During the next nine days the temperature ranged from 97° to 93°, pulse from 60 to 140, and respirations from 18 to 30 There was no further vomiting, but involuntary micturition was repeated several times a day and the bowels did not act except by enemata. He was restless during the first four days, but this was never very marked The unconsciousness continued, but he could always be roused, and at times he would utter a few incoherent words No spasms were ever noticed, nor were there any signs of paralysis though these were repeatedly looked for The pupils remained in the same state as on the day of admission The respiration was always easy, never stertorous On the morning of the tenth day the temperature rose to 101°, the pulse to 142 and the respirations to 32. He died at noon

At the necropsy we found the following Under the scalp wound and running at right angles to it, was a very fine fissure in the right parietal bone, beginning at a point on the temporal ridge midway between the anterior and the posterior borders of the bone, and running downwards and forwards, becoming wider as it did so This fissure was then continued into the anterior part of the squamous portion of the temporal bone, and into the greater wing of the sphenoid in the middle fossa of the skull The whole length of the fissure measured 4½ inches On opening the skull we found an extradural clot measuring 2½ inches × 2 inches corresponding to the temporal lobe of the brain, but the brain itself showed no flattening at this part The membranes were uniformly congested The surface of the brain was also congested and œdematous but the interior showed no changes

With a history such as that presented by this case to make a diagnosis was difficult in the extreme, since we could detect no definite signs that compression was present

---

WEST CORNWALL INFIRMARY, PENZANCE —At the 107th annual meeting of the friends of this charity, held on Jan 26th, it was stated that the late Mr T B Bolitho had bequeathed £1000 to the funds of the infirmary It was decided to use the money as a nucleus for raising a fund to provide a children s ward, which is much needed

PENSIONS FOR NURSES —In the matter of the charity hitherto known as The Institution for Nurses for Nervous and Mental Disorders of Women ' the Charity Commissioners have at the request of the original trustees promulgated a new scheme for its regulation and administration in substitution for the scheme of 1909-10 which is accordingly repealed Under the new scheme the title of the charity is to be "The Mrs Frances Sophia Caldwell Nurses Fund and the trustees are to be the corporate body called the Royal National Pension Fund for Nurses The operative clauses provide that after payment of expenses of management &c the trustees shall out of the yearly income pay an annual pension of £16 13s 4d to each of nine persons whose names are specified in a schedule, subject to this charge the income shall be applied in paying pensions at such rates as the trustees may fix having regard to the needs and circumstances of the pensioners and the [illegible] circumstances of the charity These pensioners are to be [illegible] nurses who have served for not less than 12 years in connexion with cases of nervous and mental disorders of women and are in necessitous circumstances [illegible] will be granted in the first instance for a term of three years [illegible] [illegible] three years [illegible] year the whole of the income is not expended [illegible]

SECTION OF SURGERY

The Use of Condensers in the Diagnosis, Prognosis, and Treatment of Nerve Lesions

A MEETING of this section was held on Feb 2nd, Mr J MURRAY being in the chair

Dr F HERNAMAN JOHNSON read a paper on the Use of Condensers in the Diagnosis, Prognosis, and Treatment of Nerve Lesions

Major C F BAILEY said that it should not be forgotten that the use of the condenser was only one of the methods which could be employed to estimate the degree of deviation of muscular contraction from the normal, it was, however, the most accurate It was important to determine the smallest electric discharge which would just cause the muscle to react. The test should first be applied to the corresponding normal muscle and then, the conditions being unaltered, the affected muscle should be stimulated until the first visible contraction was obtained The value of the stimulus could then be read off from the apparatus He had been using a modification of the Lewis Jones condenser whereby the electric discharge rose by increases of 25 volts from zero to 225 volts, and known resistances could also be thrown in There were two arguable questions connected with the use of condensers (*a*) whether all the muscles of the body react in a way similar to those selected by Lewis Jones, and (*b*) whether the skin resistance is really constant Certain muscles of the foot did not contract to the Lewis Jones condensers of the lowest capacity, and those of the face although they contracted to such condensers, would probably begin to do so to condensers of still lower capacity He had devised his modification to overcome this difficulty By starting with 25 volts and introducing greater resistance, examinations which would otherwise be impossible because of the pain were rendered trustworthy He agreed that the reaction of degeneration gave little information Sensory tests were also very important, and he considered that an estimation of the loss of epicritic sensibility was most valuable if properly carried out He thought that the records of many of the cases of rapid recovery of sensation after operation were largely attributable to faulty methods of testing He did not agree that a tetanising current should be used for treatment

Dr E P CUMBERBATCH said that the introduction of the condenser method marked a great advance because it measured the stimuli employed but he objected to the use of numerals in recording the results of the tests as unscientific. "Reaction of degeneration" was an incorrect term for it could be obtained in undegenerated muscle He had seen muscles which required for their contraction the largest condenser in the box and yet the patient had voluntary control over them He had found that when reaction of degeneration was present and yet voluntary power was retained the nerve was excitable to stimulation and therefore recommended that the nerve trunks should also be tested He thought that this would provide a better indication as to diagnosis and prognosis than testing muscle contraction only Observations at operations were incomplete unless the conductivity of the nerve was tested at the same time as its lesion was inspected He thought that better results would attend treatment also if the ordinary constant current were used to stimulate the nerve and attention was not devoted solely to the muscle He did not agree that it was necessary to provoke contraction in the affected muscles, the sinusoidal current produced no contraction yet cases so treated improved whether the reaction of degeneration were present or no

SECTION OF OPHTHALMOLOGY

Exhibition of Cases —Cases of the Ophthalmoscopic Appearances in [illegible] Family Idiocy —Superficial Linear Keratitis —Cataract in Experimental Thyroidectomy

A MEETING of this section was held on Feb 2nd, Mr PRIESTLEY SMITH the President being in the chair

The following cases were shown —

Mr J HERBERT FISHER Arterio venous Aneurysm

Moreover, the patient should be asked repeatedly if he has general itching or slight urticaria, or irritation in the eyes Until we find an animal suitable for experimentation, this therapy will only advance very slowly The experiences of the method already gained are, however, better than the results of a great many older methods of treatment, and this in itself may be regarded as an acquisition In this paper I have endeavoured to prove that it is possible to simplify the method of Noon and Freeman so far as to enable the practitioner to apply the vaccine in these cases without fear of obtaining less good results

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

A CASE OF FEBRIS COLOMBENSIS

By G A Lurie, M D Chicago
ATTACHED TO THE AMERICAN RED CROSS SANITARY COMMISSION IN SERBIA.

IT may be of interest to place on record a case of febris colombensis I have recently observed in Serbia. On this fever, which was first described by Castellani in Ceylon in 1905, there is very little literature, the only papers on the subject known to me, apart from Castellani's publications, being one by Fulle and one by Spaar This fever, as noted by Castellani, sometimes resembles typhoid or paratyphoid, at other times it is more like Malta fever with several relapses The onset is in most cases slow and gradual, but at times it may be quite abrupt, the general condition of the patient is usually rather severely affected, and a true typhoid state may develop, but very mild cases may also be met with No roseola or other rashes have been noted, and the spleen is seldom palpable, there may be constipation or diarrhœa. No case so far has ended fatally, but the general condition may be very severe As regards complications and sequelæ, cystitis has been noted and osteoperiostitis

The patient, an Austrian, had been prisoner in Serbia since December, 1914 There was nothing worth noting in his past medical history He never had been in the tropics At the end of June, 1915 while in Skoplje (Uskub) he began feeling tired and feverish and was seen several times by me, first as an out-patient at the American Clinique and afterwards at the Second Reserve Hospital. The fever was of a subcontinuous type, the temperature seldom exceeding 103° F, and it lasted for five weeks, terminating by lysis The general condition of the patient never was very severe. No roseola, no enlargement of the spleen no complication of any kind

The bacteriological examination of the case was carried out with the kind assistance of Mr D de Silva The blood was examined for agglutination for typhoid paratyphoid A and paratyphoid B and Malta fever four times—three times during the course of the fever and once two weeks after the fever was over, always with negative results, while it agglutinated B colombensis Ceylon strain (cultures kindly supplied by Professor Aldo Castellani) in dilutions of 1/40 1/80 and occasionally 1/160 No hæmocultures were carried out but the stools collected in a large sterile Petri dish were examined bacteriologically in the usual way by plating &c B typhosus and paratyphosus A and B were absent while 4 colonies out of 26 investigated turned out to be bacillus colombensis the others being coli and coli like bacilli

The strain isolated from this patient is identical to the Ceylon strain and corresponds in every particular to the description given by Castellani. It is a motile bacterium, Gram negative, does not liquefy either gelatin or serum On agar the growth may be typhoid like, or the germ may grow more abundantly than true typhoid The germ grows well in milk, rendering the medium acid at first, alkaline later, and often bleaching it, at times the medium may become permanently acid As regards sugar reactions, as stated by Castellani and Spaar there is no production of gas in saccharose, raffinose, adonite, inulin, inosite, amygdaline, or erythrite, while there is formation of gas in dulcite, mannite glucose, maltose, dextrin (very slight), arabinose sorbite, glycerine, isodulcite, galactose, levulose, and salicin

It is interesting to note the action on lactose I can completely confirm the previous observation made by Castellani and Spaar, that the same strain may at times produce a little gas in lactose and at other times none, while the colonies of the germ on MacConkey bilesalt lactose agar are always white, never red

The peculiar inconstant action of the germ on lactose renders its classification difficult When it does not ferment lactose, as is often the case when freshly isolated, its cultural characters are very similar to B paratyphosus B, when it produces gas in lactose it is more closely related to B coli The germ, however, as demonstrated by Castellani Fulle, and Spaar is never agglutinated by either paratyphoid B or A serum, nor by any of the many coli sera tried

There can, in my opinion, be no doubt that the case I have described is one of febris colombensis as Castellani's bacillus colombensis (1905) was isolated from the stools and the blood agglutinated strongly both the strains isolated from the patient and the original Ceylon strain, while it did not present any agglutination for the typhoid, paratyphoid A and B bacilli, and Malta fever micrococcus Moreover, the agglutination slowly and gradually decreased after the fever was over This case shows that febris colombensis is not limited to the tropics, but is found also in temperate climates and must be regarded as a cosmopolitan disease

Bibliography—Castellani Ceylon Medical Reports and Journal of the Ceylon Branch of the British Medical Association 1905 Journal of Tropical Medicine 1913, &c. Fulle Sperimentale 1914 Spaar Journal of the Ceylon Branch of the British Medical Association 1914 Journal of Tropical Medicine December 1915

CASE OF INTRACRANIAL HÆMORRHAGE WITHOUT SYMPTOMS OF COMPRESSION

By P W Lam, M B, Ch B Edin,
AND
Ed Law, M B, Ch B Edin,
RESIDENT SURGEONS DISTRICT HOSPITAL, WEST BROMWICH

IT is a matter of common knowledge that cases of head injury admitted to the casualty department of a general hospital often present difficulties in diagnosis, and the following case illustrates one of these difficulties

The patient, a man aged 32 whilst cycling down an incline on Jan 1st 1916 collided with a cart He was thrown off his bicycle and his head knocked against a post on the side of the road On admission at 9 15 A M an hour after the accident he was unconscious but could be partially aroused by strong stimuli The pulse was 76 per minute respirations 16 and temperature 99° F The pupils were equal in [illegible] dilated, and reacted sluggishly to light, the conjunctival reflex was present. The skin was cold and pale There was a wound on the right side of the scalp extending from before backwards for about 1 inch and situated over the right parietal eminence From this a small quantity of blood was oozing On probing, the wound was found to be quite superficial and no bare bone could be detected No other injuries were present except a bruise over the upper part of the left arm Two hours after admission he vomited a large quantity of coffee-coloured fluid and passed urine in bed During the next nine days the temperature ranged from 97° to 98°, pulse from 60 to 140, and respirations from 18 to 30 There was no further vomiting, but involuntary micturition was repeated several times a day and the bowels did not act except by enemata. He was restless during the first four days but this was never very marked The unconsciousness continued but he could always be roused, and at times he would utter a few incoherent words No spasms were ever noticed, nor were there any signs of paralysis though these were repeatedly looked for The pupils remained in the same state as on the day of admission The respiration was always easy, never stertorous On the morning of the tenth day the temperature rose to 101°, the pulse to 142 and the respirations to 32 He died at noon

At the necropsy we found the following Under the scalp wound and running at right angles to it was a very fine fissure in the right parietal bone beginning at a point on the temporal ridge midway between the anterior and the posterior borders of the bone, and running downwards and forwards, becoming wider as it did so This fissure was then continued into the anterior part of the squamous portion of the temporal bone, and into the greater wing of the sphenoid in the middle fossa of the skull The whole length of the fissure measured 4½ inches On opening the skull we found an extradural clot measuring 2¼ inches × 2 inches corresponding to the temporal lobe of the brain, but the brain itself showed no flattening at this part The membranes were uniformly congested The surface of the brain was also congested and œdematous but the interior showed no changes

With a history such as that presented by this case to make a diagnosis was difficult in the extreme, since we could detect no definite signs that compression was present

The Use of Condensers in the Diagnosis, Prognosis, and Treatment of Nerve Lesions

A MEETING of this section was held on Feb 2nd, Mr J MURRAY being in the chair

Dr F HERNAMAN JOHNSON read a paper on the Use of Condensers in the Diagnosis, Prognosis, and Treatment of Nerve Lesions

Major C F BAILEY said that it should not be forgotten that the use of the condenser was only one of the methods which could be employed to estimate the degree of deviation of muscular contraction from the normal, it was however, the most accurate It was important to determine the smallest electric discharge which would just cause the muscle to react. The test should first be applied to the corresponding normal muscle and then, the conditions being unaltered, the affected muscle should be stimulated until the first visible contraction was obtained The value of the stimulus could then be read off from the apparatus He had been using a modification of the *Lewis Jones condenser* whereby the electric discharge rose by increases of 25 volts from zero to 225 volts, and known resistances could also be thrown in There were two arguable questions connected with the use of condensers (*a*) whether all the muscles of the body react in a way similar to those selected by Lewis Jones, and (*b*) whether the skin resistance is really constant Certain muscles of the foot did not contract to the Lewis Jones condensers of the lowest capacity, and those of the face although they contracted to such condensers, would probably begin to do so to condensers of still lower capacity He had devised his modification to overcome this difficulty By starting with 25 volts and introducing greater resistance examinations which would otherwise be impossible because of the pain were rendered trustworthy He agreed that the reaction of degeneration gave little information Sensory tests were also very important, and he considered that an estimation of the loss of epicritic sensibility was most valuable if properly carried out He thought that the records of many of the cases of rapid recovery of sensation after operation were largely attributable to faulty methods of testing He did not agree that a tetanising current should be used for treatment

Dr E P CUMBERBATCH said that the introduction of the condenser method marked a great advance because it measured the stimuli employed but he objected to the use of numerals in recording the results of the tests as unscientific. "Reaction of degeneration" was an incorrect term for it could be obtained in undegenerated muscle He had seen muscles which required for their contraction the largest condenser in the box and yet the patient had voluntary control over them He had found that when reaction of degeneration was present and yet voluntary power was retained the nerve was excitable to stimulation, and therefore recommended that the nerve trunks should also be tested He thought that this would provide a better indication as to diagnosis and prognosis than testing muscle contraction only Observations at operations were incomplete unless the conductivity of the nerve was tested at the same time as its lesion was inspected He thought that better results would attend treatment also if the ordinary constant current were used to stimulate the nerve and attention was not devoted solely to the muscle He did not agree that it was necessary to provoke contraction in the affected muscles, the sinusoidal current produced no contraction yet cases so treated improved whether the reaction of degeneration were present or not

SECTION OF OPHTHALMOLOGY

Exhibition of Cases—Cases of the Ophthalmoscopic Appearances in [illegible] Idiocy—Superficial Linear [illegible]—Cataract in Experimental Thyroidectomy

A MEETING of this section was held on Feb 2nd, Mr PRIESTLEY SMITH, the President, being in the chair

The following cases were shown:—

Mr J HERBERT FISHER Arterio venous Aneurysm

Mr Arnold Lawson Coloboma of the Upper Eyelid
Dr J Attlee Congenital Dermoid of the Conjunctiva
Mr G H Pooley Lymphoma of Orbits

A paper by the late Mr George Coats was read by Mr R Affleck Greeves, entitled "The Cause of the Ophthalmoscopic Appearances in Amaurotic Family Idiocy" The writer in this paper deals with a contribution by Dr F E Batten and Mr Stephen Mayou on Family Cerebral Degeneration with Macular Change, in which those authors state that there is a close relationship between these cases and the instances of amaurotic family idiocy, the only difference between them being that the macular region in amaurotic family idiocy shows a much more marked œdema of the internuclear layers, and therefore a white area around the macula associated with a hole or thinning of the retina at the fovea due to œdema, their conclusion being that œdema of the internuclear layers was present in both diseases, but much more markedly in amaurotic family idiocy In the present paper it was stated that for a histological study of the retina the material must be absolutely fresh, as post-mortem changes begin two hours after death, fixation must be perfect (Zenker's solution being the best), and the method of cutting must be suitable Mr Coats considered that in the retina, apart from the occurrence of œdema, the macular changes show marked differences in the two diseases, and these were enumerated He repudiated the view which had been ascribed to him that the ophthalmoscopic appearances in amaurotic family idiocy are due to coagulation necrosis Though the particular form of chromolysis vacuolisation, &c, which characterise family cerebral degeneration closely simulates that which is seen in amaurotic family idiocy the underlying cause may be different, and the race selectiveness of amaurotic family idiocy should cause hesitation in identifying it with a disease which is not race selective —Mr S Mayou, in discussing the paper, agreed that formalin, which was used in the case described by Dr Batten and himself, was not a good fixative, but in one of the cases reported he thought the appearances could be fairly relied upon, except in regard to œdema in the internuclear layers —Mr E Treacher Collins thought the paper might well have been entitled "Causes of Opacity of the Retina," as it dealt with the wider subject In the class of case investigated by Mr Coats he seemed to have established that the opacity of the retina was due to a change in the ganglion cells —Mr J H Parsons said he had cut sections from a case of amaurotic family idiocy, and there were large œdematous spaces similar to those in Dr Batten's and Mr Mayou's case and he did not think they could be explained merely as the result of bad fixation. A good fixative, like the Zenker, might cause an artefact appearance in the opposite direction to that alleged in this paper He regarded amaurotic family idiocy as one of the most sharply defined clinical entities known

Mr Holmes Spicer and Mr Affleck Greeves contributed a paper on Superficial Linear Keratitis The condition was one in which there were superficial ridges of epithelium raised above the level of the cornea mostly running in vertical lines, grey and tapering, and having along their course bulging node like appearances They had tapering ends and did not extend quite to the limbus They not uncommonly showed punctate staining but there was no iritis The tension of the eyeball was nearly always minus and during such times the vision was definitely impaired, though it recovered when the normal tension was re-established It differed from dendritic ulcer (which it appeared to simulate) especially in the reduced tension No measures which he had employed prevented recurrences A number of drawings and microphotographs illustrated the contribution —The paper was discussed by Mr J Cole Marshall, Mr J B Lawford, and Mr D L Davies

Mr Walter Edmunds read a paper on Cataract in Experimental Thyroidectomy He said he did not think the lens opacity was due to disease of the eye itself, in the dogs dealt with the pupil was active, and there was perception of light. He thought the cataract was due to the general nutritional changes following the removal of the thyroid gland, and the fits seemed to be due to that. Similar instances had been recorded in man The cataractous changes which he found were not of the lamellar or any special type. When the parathyroids were also removed, the animal quickly sickened and died the death being preceded by tremors —The paper was discussed by Mr Parsons and Mr Fisher, and Mr Edmunds replied

WEST LONDON MEDICO CHIRURGICAL SOCIETY

Exhibition of Specimens and Skiagrams

A pathological meeting of this society was held on Feb 4th, Dr Leonard Dobson, the President, being in the chair

The President showed a specimen and microscopic section of Sarcoma of the Brain situated in the posterior part of the left middle frontal convolution The first symptom in this case was an epileptic fit on Dec. 18th followed by amnesia, aphasia, right hemiplegia, and death on Jan 23rd The patient was a man aged 47

Dr J M Bernstein showed the following specimens 1 Syphilitic Liver from a male child aged 7 months 2 Large Aneurysm of Arch of Aorta 3 Hodgkin's Disease showing Lymphoma of Breast 4 Perforation of Œsophagus from fish bone, death from acute suppurative mediastinitis 5 Polycystic Kidney 6 Primary Sarcoma of Root of Lung, secondary growth in liver He also described a case of Acute Lymphatic Leukæmia, from which he showed a blood film

Dr Arthur Saunders showed 1 A kidney from a case of Acute Suppurative Nephritis affecting one kidney only in a child aged 1 year 2 With Mr H Tyrrell Gray a Parovarian Cyst from a child aged 2 years 3 With Dr Reginald Morton, a specimen and skiagram of a large Aortic Aneurysm.

Major W McAdam Eccles R A.M C (T F), showed 1 A microscopic section and skiagrams from a case of Mammary Tumour associated with a lesion of the tibia in a female aged 34 In this patient the head of the left fibula was found, on examination by Major McAdam Eccles, to be lying outside the external condyle of the femur, the shaft of the left tibia appeared to be displaced outwards and somewhat upwards, although the proximal epiphyseal part of the bone seemed to retain its normal relationship to the condyles of the femur Examination of the right knee revealed a somewhat similar condition but in a much earlier stage, the fibula being in its normal position but the tibia having distinct rarefaction A section of tissue removed from the breast showed typical atrophic scirrhus while that from the tibia gave no evidence of any neoplasm primary or secondary 2 Skiagrams of two wedge-shaped dorsal vertebræ from a male aged 28, no signs of any inflammatory mischief nor of any real "crushing"

Mr H S Souttar showed the following specimens 1 Elephantiasis of Vulva, huge mass excised, patient eight months pregnant, later, normal confinement The patient was aged 35 2 Complete Prostatic Tumour removed by suprapubic operation from a patient aged 70 3 Cystic Adenoma of Thyroid from a female aged 26 4 Scirrhous Carcinoma of Breast, the patient was aged 50 5 Carcinoma of Stomach, operation, partial gastrectomy and posterior gastro-jejunostomy, the patient was a male aged 65 6 Large Nævo-lipoma of Face removed by excision Mr Souttar said that the patient in this case a male aged 21, had those other congenital defects—viz (*a*) spina bifida occulta over sacrum, (*b*) gross scoliosis defective vertebra (first lumbar), (*c*) multiple nævo-lipomata on back, (*d*) aortic stenosis, (*e*) mitral regurgitation, (*f*) ? patent foramen ovale

Mr O L Addison described a case of Aneurysm of the Radial Artery at the back of the wrist in a female aged 73

Dr George Pernet showed (1) Cultures of Favus in various media from the case of a child whose mother had suffered from favus for 30 years, (2) cultures of Ringworm, and (3) cultures of Streptothrix to compare with megalosporon ringworm

Major J M Atkinson, R A M C (T F) showed several skiagrams of injuries to bones due to shell

Mr H Tyrrell Gray showed the following skiagrams (1) Congenital scoliosis half lumbar vertebra only, (2) congenital absence of half the eighth and eleventh dorsal vertebræ 13 ribs on one side and 12 ribs on the opposite side congenital scoliosis, (3) congenital scoliosis defective development of half the fifth dorsal vertebra, (4) spina bifida occulta fourth lumbar vertebra, (5) congenital club-hand, (6) unusual type of tuberculous hip disease, (7) scoliosis in a boy due to shortening of one leg of which the bones show a condition resembling fibro-cystic disease, and (8) tuberculous arthritis of ankle-joint.

Mr ARNOLD LAWSON *Coloboma of the Upper Eyelid.*
Dr J ATTLEE *Congenital Dermoid of the Conjunctiva*
Mr G H POOLEY *Lymphoma of Orbits*

A paper by the late Mr GEORGE COATS was read by Mr R AFFLECK GREEVES, entitled "The Cause of the Ophthalmoscopic Appearances in Amaurotic Family Idiocy" The writer in this paper deals with a contribution by Dr F E Batten and Mr Stephen Mayou on Family Cerebral Degeneration with Macular Change, in which those authors state that there is a close relationship between these cases and the instances of amaurotic family idiocy, the only difference between them being that the macular region in amaurotic family idiocy shows a much more marked œdema of the internuclear layers, and therefore a white area around the macula associated with a hole or thinning of the retina at the fovea due to œdema, their conclusion being that œdema of the internuclear layers was present in both diseases, but much more markedly in amaurotic family idiocy In the present paper it was stated that for a histological study of the retina the material must be absolutely fresh, as post-mortem changes begin two hours after death, fixation must be perfect (Zenker s solution being the best), and the method of cutting must be suitable Mr Coats considered that in the retina, apart from the occurrence of œdema, the macular changes show marked differences in the two diseases, and these were enumerated He repudiated the view which had been ascribed to him that the ophthalmoscopic appearances in amaurotic family idiocy are due to coagulation necrosis Though the particular form of chromolysis, vacuolisation, &c, which characterise family cerebral degeneration closely simulates that which is seen in amaurotic family idiocy the underlying cause may be different, and the race selectiveness of amaurotic family idiocy should cause hesitation in identifying it with a disease which is not race selective —Mr S MAYOU, in discussing the paper, agreed that formalin, which was used in the case described by Dr Batten and himself, was not a good fixative, but in one of the cases reported he thought the appearances could be fairly relied upon, except in regard to œdema in the internuclear layers —Mr E TREACHER COLLINS thought the paper might well have been entitled "Causes of Opacity of the Retina," as it dealt with the wider subject In the class of case investigated by Mr Coats he seemed to have established that the opacity of the retina was due to a change in the ganglion cells —Mr J H PARSONS said he had cut sections from a case of amaurotic family idiocy, and there were large œdematous spaces similar to those in Dr Batten's and Mr Mayou's case, and he did not think they could be explained merely as the result of bad fixation A good fixative, like the Zenker, might cause an artefact appearance in the opposite direction to that alleged in this paper He regarded amaurotic family idiocy as one of the most sharply defined clinical entities known

Mr HOLMES SPICER and Mr AFFLECK GREEVES contributed a paper on Superficial Linear Keratitis The condition was one in which there were superficial ridges of epithelium raised above the level of the cornea, mostly running in vertical lines, grey and tapering, and having along their course bulging node-like appearances They had tapering ends and did not extend quite to the limbus They not uncommonly showed punctate staining but there was no iritis The tension of the eyeball was nearly always minus and during such times the vision was definitely impaired, though it recovered when the normal tension was re-established It differed from dendritic ulcer (which it appeared to simulate) especially in the reduced tension. No measures which he had employed prevented recurrences A number of drawings and microphotographs illustrated the contribution —The paper was discussed by Mr J COLE MARSHALL Mr J B LAWFORD, and Mr D L DAVIES

Mr WALTER EDMUNDS read a paper on Cataract in Experimental Thyroidectomy He said he did not think the lens opacity was due to disease of the eye itself, in the dogs dealt with the pupil was active, and there was perception of light. He thought the cataract was due to the general nutritional changes following the removal of the thyroid gland and the fits seemed to be due to that. Similar instances had been recorded in man The cataractous changes which he found were not of the lamellar or any special type When the parathyroids were also removed, the animal quickly sickened and died, the death being preceded by tremors —The paper was discussed by Mr PARSONS and Mr FISHER, and Mr EDMUNDS replied

WEST LONDON MEDICO-CHIRURGICAL SOCIETY

Exhibition of Specimens and Skiagrams

A PATHOLOGICAL meeting of this society was held on Feb 4th, Dr LEONARD DOBSON, the President being in the chair

The PRESIDENT showed a specimen and microscopic section of Sarcoma of the Brain situated in the posterior part of the left middle frontal convolution The first symptom in this case was an epileptic fit on Dec. 18th, followed by amnesia, aphasia, right hemiplegia, and death on Jan 23rd The patient was a man aged 47

Dr J M BERNSTEIN showed the following specimens 1 Syphilitic Liver from a male child aged 7 months 2 Large Aneurysm of Arch of Aorta 3 Hodgkin's Disease showing Lymphoma of Breast. 4 Perforation of Œsophagus from fish bone, death from acute suppurative mediastinitis 5 Polycystic Kidney 6 Primary Sarcoma of Root of Lung, secondary growth in liver He also described a case of Acute Lymphatic Leukæmia, from which he showed a blood film

Dr ARTHUR SAUNDERS showed 1 A kidney from a case of Acute Suppurative Nephritis affecting one kidney only in a child aged 1 year 2 With Mr H Tyrrell Gray, a Parovarian Cyst from a child aged 2 years 3 With Dr Reginald Morton, a specimen and skiagram of a large Aortic Aneurysm.

Major W MCADAM ECCLES, R A M C (T F), showed 1 A microscopic section and skiagrams from a case of Mammary Tumour associated with a lesion of the tibia in a female aged 34 In this patient the head of the left fibula was found, on examination by Major McAdam Eccles, to be lying outside the external condyle of the femur, the shaft of the left tibia appeared to be displaced outwards and somewhat upwards, although the proximal epiphyseal part of the bone seemed to retain its normal relationship to the condyles of the femur Examination of the right knee revealed a somewhat similar condition but in a much earlier stage, the fibula being in its normal position but the tibia having distinct rarefaction A section of tissue removed from the breast showed typical atrophic scirrhus while that from the tibia gave no evidence of any neoplasm, primary or secondary 2 Skiagrams of two wedge shaped dorsal vertebræ from a male aged 28, no signs of any inflammatory mischief nor of any real "crushing"

Mr H S SOUTTAR showed the following specimens 1 Elephantiasis of Vulva, huge mass excised, patient eight months pregnant, later normal confinement The patient was aged 35 2 Complete Prostatic Tumour removed by suprapubic operation from a patient aged 70 3 Cystic Adenoma of Thyroid from a female aged 26 4 Scirrhous Carcinoma of Breast, the patient was aged 50 5 Carcinoma of Stomach, operation partial gastrectomy and posterior gastro jejunostomy, the patient was a male aged 65 6 Large Nævo-lipoma of Face removed by excision Mr Souttar said that the patient in this case, a male aged 21, had those other congenital defects—viz, (a) spina bifida occulta over sacrum, (b) gross scoliosis defective vertebra (first lumbar), (c) multiple nævo-lipomata on back, (d) aortic stenosis, (e) mitral regurgitation, (f) ? patent foramen ovale

Mr O L ADDISON described a case of Aneurysm of the Radial Artery at the back of the wrist in a female aged 73

Dr GEORGE PERNET showed (1) Cultures of Favus in various media from the case of a child whose mother had suffered from favus for 30 years, (2) cultures of Ringworm, and (3) cultures of Streptothrix to compare with megalosporon ringworm

Major J M ATKINSON, R A M C (T F) showed several skiagrams of injuries to bones due to shell

Mr H TYRRELL GRAY showed the following skiagrams (1) Congenital scoliosis half lumbar vertebra only, (2) congenital absence of half the eighth and eleventh dorsal vertebræ 13 ribs on one side and 12 ribs on the opposite side congenital scoliosis, (3) congenital scoliosis defective development of half the fifth dorsal vertebra, (4) spina bifida occulta, fourth lumbar vertebra, (5) congenital [illegible] band, (6) unusual type of tuberculous hip disease, (7) scoliosis in a boy due to shortening of one leg of which the bones show a condition resembling fibro-cystic disease, and (8) tuberculous arthritis of ankle-joint

Dr REGINALD MORTON showed the following skiagrams (1) Large aneurysm of arch of aorta, male aged 41, to illustrate radiographically Dr Bernstein's specimen, (2) branched calculus in the pelvis of the right kidney, female aged 37, under the care of Mr Souttar, (3) showing absorption of bodies of the fourth and fifth lumbar vertebræ following an attack of paratyphoid, for comparison with Major McAdam Eccles's skiagram showing wedge-shaped vertebræ, male aged 30, under the care of Dr Saunders, (4) wrist showing changes in bones and joint spaces due to sepsis, male aged 24, (5) osteo-arthritis of left hip male aged 43, under the care of Mr Tyrrell Gray, (6) rarefying osteitis of upper end of tibia and fibula, female aged 37, under the care of Mr Addison, (7) pathological dislocation of right hip from tuberculous disease male aged 10, under the care of Mr Addison, (8) skiagram showing early tuberculous invasion of lungs—striæ and mottling close in around the hilum, the periphery of the lungs clear The detail in the latter skiagram was extremely fine, and this exhibit gave rise to an interesting discussion, in which the PRESIDENT, Dr SAUNDERS, Mr ADDISON, Dr MORTON, and other members took part, on the value of radiography as a means of detecting pulmonary tuberculosis in its earliest stages, before physical signs make themselves apparent

The PRESIDENT, Major MCADAM ECCLES Mr ADDISON, Mr TYRRELL GRAY, Dr SAUNDERS Dr H PERCY POTTER Mr RICKARD W LLOYD, Dr BERNSTEIN Dr MORTON and others discussed the various specimens and skiagrams shown at the meeting

FULHAM MILITARY HOSPITAL —A clinical meeting of the staff of this hospital was held on Jan 11th, Major O T Parsons the Officer Commanding, being in the chair —Dr S H Belfrage opened a discussion on Septic Compound Fractures due to Gunshot Wounds He outlined the chief indications for treatment as being (1) Vigorous treatment of the sepsis, (2) the securing of comfort to the patient and ease of nursing, (3) early movement of the joints, and (4) correction of deformity He had found the ordinary splints of little use and anticipated much help from Hey Groves's modification of Hodgen He emphasised the desirability of paying more attention to obtaining a useful limb than to accurate apposition of the fragments It was doubtful whether extension could be usefully employed in the early stages, later on the fragments could be adjusted under an anæsthetic —Mr H Chapple pointed out a fundamental difference in the treatment of fractures of the upper and lower extremities In the arm the exact position of the fragments was often not of vital importance in the securing of a useful limb, but in the leg the necessity of parallelism for walking dictated the greatest care as to their position He advocated operation where the disturbance of the fragments rendered it necessary, but in septic cases it was essential to wait until the sepsis had been dealt with before attempting plating He also referred to a great truth established by Sir Arbuthnot Lane, that in dealing with a much comminuted fracture it was not necessary to get the whole circumference of the ends approximated If a small portion were put in apposition the gap would be filled by new bone laid down, if the after treatment were suitable —Captain J R Lee said that generally there was too much haste to remove sequestra They should be left till complete separation occurred as frequently an apparent sequestrum proved to be a focus of new bone formation He wished to emphasise the importance in the treatment of sepsis of leaving or if need be making, a very widely open wound, and meantime the surgeon should not be too anxious about the displacement of the fragments —Dr Carnegie Dickson referred to the extreme rapidity with which cancellous tissue can be absorbed to make room for active marrow in acute general diseases, and with regard to the question of the duration of a septic focus alluded to a case in which a projectile had been removed six months after complete healing but in which at the operation pus was found containing organisms of feeble vitality but still capable of growth —Dr Kinnier Wilson in discussing after results, expressed the opinion that in some cases the disability of muscular movement was greater than could be explained by mere disuse He considered that some cases were explicable on the theory that a defect was present in the reflex arc through the spinal cord Possibly the constant afferent impulses from the diseased focus produced a dynamic functional change in the anterior horn cells and consequent muscular atrophy Electrical treatment in such cases was more important than massage Repeated efforts on the part of the patient sometimes sufficed to reawake innervation through the replex arc.—The Chairman dwelt on the debt the surgeon owed to X rays and advocated putting up fractures under X ray illumination He was more inclined to the use of splinting than some speakers, as he considered the prevention of movement in the injured tissues was of great value in limiting sepsis The joint involved in a septic process required immobilisation, while the other joints required to be moved He considered continuous extension valuable and that often the weight applied was too small, attempts should be made from the first to rectify deformities With regard to the all important point of treating sepsis, he referred to the value of transverse incisions which tended to remain gaping The introduction of solid sodium chloride, which had given good results in France should be tried, as also solid urea, on which Professor W St Clair Symmers, of Belfast, had reported favourably [1] He had obtained good results in septic conditions by Bier's treatment before the war, and thought greater use might be made of it

BRADFORD MEDICO-CHIRURGICAL SOCIETY —A meeting of this society was held on Jan 18th, Dr J T Kitchin being in the chair —Dr F W Eurich showed microscopical sections and a case of Charcot's Disease of the Spinal Column —Dr T Jason Wood showed pathological specimens and read notes of two cases of Abdominal Disease in Children 1 A fine healthy child aged 1 year, with the symptoms of intussusception At the operation a large tuberculous mass was found in the mesentery causing kinking of the intestine Lateral anastomosis was performed and the child made a perfect recovery 2 A case of intestinal obstruction which at the operation was found to be caused by a mesenteric cyst which by dragging on the intestine had formed a sort of volvulus —Dr H Vallow read a paper on Tuberculosis Arrangements from the Clinical Point of View His conclusions were as follows There should be a panel of practitioners always on the look out for cases of tuberculosis a tuberculosis dispensary equipped with all the apparatus requisite for the early diagnosis of tubercle with a staff that has the confidence of the medical practitioners of the district, a sanatorium where the early hopeful cases can be sent to, a hospital for the more advanced cases, a home for the dying, a residential open air school for the children, an open air school for the children Provision must be made for the home treatment of patients, with adequate nursing visitation, and after care in all its forms It may also be necessary to have farm colonies or cottages on the outskirts of the town where patients can sleep in the pure air institutions for the treatment of surgical tuberculosis, and provision for the treatment of cases at the dispensary It is also necessary for the local authorities to pay as much attention to the purification of the air supply as they do to the water supply It is necessary for all these institutions to be clinically efficient, and for the medical officer of health, the tuberculosis officer the practitioners, and the various help committees to unite together in face of the common foe

THE ANGLO-RUSSIAN HOSPITAL —The Anglo-Russian Hospital at Petrograd which is under the patronage of Queen Alexandra, was formally opened on Feb 1st in the presence of the Empress Marie, the Grand Duchesses Olga and Tatiana, the Grand Duke Andrew Vladimirovitch, the British Ambassador and Lady Buchanan The hospital will contain 200 beds Lady Muriel Paget is the honorary organising secretary

Dr Alan McDougall has been awarded a special testimonial by the Royal Humane Society for his rescue work at the time of the sledging disaster at the Manchester Epileptic Colony Sandle Bridge The award states that he plunged into the water without taking off his clothing and saved three patients nearly losing his own life in so doing

---

[1] THE LANCET Dec. 4th 1915 p 1237

Mr **ARNOLD LAWSON** Coloboma of the Upper Eyelid
Dr J **ATTLEE** Congenital Dermoid of the Conjunctiva
Mr G H **POOLEY** Lymphoma of Orbits

A paper by the late Mr **GEORGE COATS** was read by Mr R **AFFLECK GREEVES**, entitled "The Cause of the Ophthalmoscopic Appearances in Amaurotic Family Idiocy" The writer in this paper deals with [a contribution by Dr F E Batten and Mr Stephen Mayou on Family Cerebral Degeneration with Macular Change, in which those authors state that there is a close relationship between these cases and the instances of amaurotic family idiocy, the only difference between them being that the macular region in amaurotic family idiocy shows a much more marked œdema of the internuclear layers, and therefore a white area around the macula associated with a hole or thinning of the retina at the fovea due to œdema, their conclusion being that œdema of the internuclear layers was present in both diseases, but much more markedly in amaurotic family idiocy In the present paper it was stated that for a histological study of the retina the material must be absolutely fresh, as post-mortem changes begin two hours after death, fixation must be perfect (Zenker's solution being the best), and the method of cutting must be suitable Mr Coats considered that in the retina, apart from the occurrence of œdema, the macular changes show marked differences in the two diseases, and these were enumerated. He repudiated the view which had been ascribed to him that the ophthalmoscopic appearances in amaurotic family idiocy are due to coagulation necrosis Though the particular form of chromolysis, vacuolisation, &c, which characterise family cerebral degeneration closely simulates that which is seen in amaurotic family idiocy the underlying cause may be different, and the race selectiveness of amaurotic family idiocy should cause hesitation in identifying it with a disease which is not race selective —Mr S **MAYOU**, in discussing the paper, agreed that formalin, which was used in the case described by Dr Batten and himself, was not a good fixative, but in one of the cases reported he thought the appearances could be fairly relied upon, except in regard to œdema in the internuclear layers —Mr E **TREACHER COLLINS** thought the paper might well have been entitled "Causes of Opacity of the Retina," as it dealt with the wider subject In the class of case investigated by Mr Coats he seemed to have established that the opacity of the retina was due to a change in the ganglion cells —Mr J H **PARSONS** said he had cut sections from a case of amaurotic family idiocy, and there were large œdematous spaces similar to those in Dr Batten's and Mr Mayou's case, and he did not think they could be explained merely as the result of bad fixation A good fixative, like the Zenker, might cause an artefact appearance in the opposite direction to that alleged in this paper He regarded amaurotic family idiocy as one of the most sharply defined clinical entities known

Mr **HOLMES SPICER** and Mr **AFFLECK GREEVES** contributed a paper on Superficial Linear Keratitis The condition was one in which there were superficial ridges of epithelium raised above the level of the cornea mostly running in vertical lines, grey and tapering and having along their course bulging node like appearances They had tapering ends and did not extend quite to the limbus They not uncommonly showed punctate staining, but there was no iritis The tension of the eyeball was nearly always minus and during such times the vision was definitely impaired, though it recovered when the normal tension was re-established It differed from dendritic ulcer (which it appeared to simulate) especially in the reduced tension. No measures which he had employed prevented recurrences A number of drawings and microphotographs illustrated the contribution —The paper was discussed by Mr J **COLE MARSHALL**, Mr J B **LAWFORD**, and Mr D L **DAVIES**

Mr **WALTER EDMUNDS** read a paper on Cataract in Experimental Thyroidectomy He said he did not think the lens opacity was due to disease of the eye itself, in the dogs dealt with the pupil was active, and there was perception of light He thought the cataract was due to the general nutritional changes following the removal of the thyroid gland, and the fits seemed to be due to that Similar instances had been recorded in man The cataractous changes which he found were not of the lamellar or any special type When the parathyroids were also removed, the animal quickly sickened and died the death being preceded by tremors —The paper was discussed by Mr **PARSONS** and Mr **FISHER**, and Mr **EDMUNDS** replied

WEST LONDON MEDICO-CHIRURGICAL SOCIETY

Exhibition of Specimens and Skiagrams

A **PATHOLOGICAL** meeting of this society was held on Feb 4th, Dr **LEONARD DOBSON**, the President, being in the chair

The **PRESIDENT** showed a specimen and microscopic section of Sarcoma of the Brain situated in the posterior part of the left middle frontal convolution The first symptom in this case was an epileptic fit on Dec. 18th, followed by amnesia, aphasia, right hemiplegia, and death on Jan 23rd The patient was a man aged 47

Dr J M **BERNSTEIN** showed the following specimens 1 Syphilitic Liver from a male child aged 7 months 2 Large Aneurysm of Arch of Aorta 3 Hodgkin's Disease showing Lymphoma of Breast 4 Perforation of Œsophagus from fish bone, death from acute suppurative mediastinitis 5 Polycystic Kidney 6 Primary Sarcoma of Root of Lung, secondary growth in liver He also described a case of Acute Lymphatic Leukæmia, from which he showed a blood film

Dr **ARTHUR SAUNDERS** showed 1 A kidney from a case of Acute Suppurative Nephritis affecting one kidney only in a child aged 1 year 2. With Mr H Tyrrell Gray, a Parovarian Cyst from a child aged 2 years 3 With Dr Reginald Morton, a specimen and skiagram of a large Aortic Aneurysm

Major W **McADAM ECCLES**, R A.M C (T F), showed 1. A microscopic section and skiagrams from a case of Mammary Tumour associated with a lesion of the tibia in a female aged 34 In this patient the head of the left fibula was found, on examination by Major McAdam Eccles, to be lying outside the external condyle of the femur, the shaft of the left tibia appeared to be displaced outwards and somewhat upwards, although the proximal epiphyseal part of the bone seemed to retain its normal relationship to the condyles of the femur Examination of the right knee revealed a somewhat similar condition but in a much earlier stage, the fibula being in its normal position but the tibia having distinct rarefaction A section of tissue removed from the breast showed typical atrophic scirrhus, while that from the tibia gave no evidence of any neoplasm, primary or secondary 2 Skiagrams of two wedge shaped dorsal vertebræ from a male aged 28, no signs of any inflammatory mischief nor of any real "crushing"

Mr H S **SOUTTAR** showed the following specimens 1 Elephantiasis of Vulva, huge mass excised, patient eight months pregnant, later, normal confinement The patient was aged 35 2 Complete Prostatic Tumour removed by suprapubic operation from a patient aged 70 3 Cystic Adenoma of Thyroid from a female aged 26 4 Scirrhous Carcinoma of Breast, the patient was aged 50 5 Carcinoma of Stomach, operation partial gastrectomy and posterior gastro-jejunostomy, the patient was a male aged 65 6 Large Nævo-lipoma of Face removed by excision Mr Souttar said that the patient in this case a male aged 21, had those other congenital defects—viz, (*a*) spina bifida occulta over sacrum, (*b*) gross scoliosis defective vertebra (first lumbar), (*c*) multiple nævo-lipomata on back, (*d*) aortic stenosis, (*e*) mitral regurgitation, (*f*) ? patent foramen ovale

Mr O L **ADDISON** described a case of Aneurysm of the Radial Artery at the back of the wrist in a female aged 73

Dr **GEORGE PERNET** showed (1) Cultures of Favus in various media from the case of a child whose mother had suffered from favus for 30 years, (2) cultures of Ringworm and (3) cultures of Streptothrix to compare with megalosporon ringworm

Major J M **ATKINSON**, R A M C (T F) showed several skiagrams of injuries to bones due to shell

Mr H **TYRRELL GRAY** showed the following skiagrams (1) Congenital scoliosis half lumbar vertebra only, (2) congenital absence of half the eighth and eleventh dorsal vertebræ, 13 ribs on one side and 12 ribs on the opposite side congenital scoliosis, (3) congenital scoliosis defective development of half the fifth dorsal vertebra, (4) spina bifida occulta fourth lumbar vertebra, (5) congenital cleft hand, (6) unusual type of tuberculous hip disease, (7) scoliosis in a boy due to shortening of one leg, of which the bones show a condition resembling fibro-cystic disease, and (8) tuberculous arthritis of ankle-joint

Dr REGINALD MORTON showed the following skiagrams (1) Large aneurysm of arch of aorta, male aged 41, to illustrate radiographically Dr Bernstein's specimen, (2) branched calculus in the pelvis of the right kidney, female aged 37, under the care of Mr Souttar, (3) showing absorption of bodies of the fourth and fifth lumbar vertebræ following an attack of paratyphoid, for comparison with Major McAdam Eccles's skiagram showing wedge shaped vertebræ, male aged 30, under the care of Dr Saunders, (4) wrist showing changes in bones and joint spaces due to sepsis, male aged 24, (5) osteo-arthritis of left hip, male aged 43, under the care of Mr Tyrrell Gray, (6) rarefying osteitis of upper end of tibia and fibula, female aged 37, under the care of Mr Addison, (7) pathological dislocation of right hip from tuberculous disease, male aged 10, under the care of Mr Addison, (8) skiagram showing early tuberculous invasion of lungs—striæ and mottling close in around the hilum, the periphery of the lungs clear The detail in the latter skiagram was extremely fine, and this exhibit gave rise to an interesting discussion, in which the PRESIDENT, Dr SAUNDERS, Mr ADDISON, Dr MORTON, and other members took part, on the value of radiography as a means of detecting pulmonary tuberculosis in its earliest stages, before physical signs make themselves apparent

The PRESIDENT, Major MCADAM ECCLES Mr ADDISON, Mr TYRRELL GRAY, Dr SAUNDERS Dr H. PERCY POTTER, Mr RICKARD W LLOYD, Dr BERNSTEIN, Dr MORTON, and others discussed the various specimens and skiagrams shown at the meeting

---

FULHAM MILITARY HOSPITAL —A clinical meeting of the staff of this hospital was held on Jan 11th, Major C T Parsons, the Officer Commanding, being in the chair —Dr S H Belfrage opened a discussion on Septic Compound Fractures due to Gunshot Wounds He outlined the chief indications for treatment as being (1) Vigorous treatment of the sepsis, (2) the securing of comfort to the patient and ease of nursing, (3) early movement of the joints, and (4) correction of deformity He had found the ordinary splints of little use and anticipated much help from Hey Groves's modification of Hodgen He emphasised the desirability of paying more attention to obtaining a useful limb than to accurate apposition of the fragments It was doubtful whether extension could be usefully employed in the early stages, later on the fragments could be adjusted under an anæsthetic —Mr H Chapple pointed out a fundamental difference in the treatment of fractures of the upper and lower extremities In the arm the exact position of the fragments was often not of vital importance in the securing of a useful limb, but in the leg the necessity of parallelism for walking dictated the greatest care as to their position He advocated operation where the disturbance of the fragments rendered it necessary, but in septic cases it was essential to wait until the sepsis had been dealt with before attempting plating He also referred to a great truth established by Sir Arbuthnot Lane, that in dealing with a much comminuted fracture it was not necessary to get the whole circumference of the ends approximated If a small portion were put in apposition the gap would be filled by new bone laid down, if the after treatment were suitable —Captain J R Lee said that generally there was too much haste to remove sequestra They should be left till complete separation occurred as frequently an apparent sequestrum proved to be a focus of new bone formation He wished to emphasise the importance in the treatment of sepsis of leaving or if need be making, a very widely open wound, and meantime the surgeon should not be too anxious about the displacement of the fragments —Dr Carnegie Dickson referred to the extreme rapidity with which cancellous tissue can be absorbed to make room for active marrow in acute general diseases, and with regard to the question of the duration of a septic focus alluded to a case in which a projectile had been removed six months after complete healing, but in which at the operation pus was found containing organisms of feeble vitality but still capable of growth —Dr Kinnier Wilson in discussing after results, expressed the opinion that in some cases the disability of muscular movement was greater than could be explained by mere disuse He considered that some cases were explicable on the theory that a defect was present in the reflex arc through the spinal cord Possibly the constant afferent impulses from the diseased focus produced a dynamic functional change in the anterior horn cells and consequent muscular atrophy Electrical treatment in such cases was more important than massage Repeated efforts on the part of the patient sometimes sufficed to reawake innervation through the replex arc.—The Chairman dwelt on the debt the surgeon owed to X rays and advocated putting up fractures under X ray illumination He was more inclined to the use of splinting than some speakers, as he considered the prevention of movement in the injured tissues was of great value in limiting sepsis The joint involved in a septic process required immobilisation, while the other joints required to be moved He considered continuous extension valuable and that often the weight applied was too small, attempts should be made from the first to rectify deformities With regard to the all important point of treating sepsis, he referred to the value of transverse incisions, which tended to remain gaping The introduction of solid sodium chloride, which had given good results in France should be tried, as also solid urea, on which Professor W St Clair Symmers, of Belfast, had reported favourably[1] He had obtained good results in septic conditions by Bier's treatment before the war, and thought greater use might be made of it

---

BRADFORD MEDICO-CHIRURGICAL SOCIETY —A meeting of this society was held on Jan 18th, Dr J T Kitchin being in the chair —Dr F W Eurich showed microscopical sections and a case of Charcot's Disease of the Spinal Column —Dr T Jason Wood showed pathological specimens and read notes of two cases of Abdominal Disease in Children 1. A fine healthy child, aged 1 year, with the symptoms of intussusception At the operation a large tuberculous mass was found in the mesentery causing kinking of the intestine Lateral anastomosis was performed and the child made a perfect recovery 2 A case of intestinal obstruction which at the operation was found to be caused by a mesenteric cyst which by dragging on the intestine had formed a sort of volvulus —Dr H Vallow read a paper on Tuberculosis Arrangements from the Clinical Point of View His conclusions were as follows There should be a panel of practitioners always on the look out for cases of tuberculosis, a tuberculosis dispensary equipped with all the apparatus requisite for the early diagnosis of tubercle with a staff that has the confidence of the medical practitioners of the district, a sanatorium where the early hopeful cases can be sent to, a hospital for the more advanced cases, a home for the dying, a residential open air school for the children, an open air school for the children Provision must be made for the home treatment of patients, with adequate nursing, visitation, and after care in all its forms It may also be necessary to have farm colonies or cottages on the outskirts of the town where patients can sleep in the pure air, institutions for the treatment of surgical tuberculosis, and provision for the treatment of cases at the dispensary It is also necessary for the local authorities to pay as much attention to the purification of the air supply as they do to the water supply It is necessary for all these institutions to be clinically efficient, and for the medical officer of health, the tuberculosis officer, the practitioners, and the various help committees to unite together in face of the common foe

Reviews and Notices of Books.

Post mortem Methods (Cambridge Public Health Series)

By J MARTIN BEATTIE, M A., M D Edin, Professor of Bacteriology, University of Liverpool, formerly Joseph Hunter Professor of Pathology, University of Sheffield. With three figures in the text and eight plates Cambridge University Press 1915 Pp 231 Price 10s 6d

THE volumes of the Cambridge Public Health Series which have already appeared have been characterised by accuracy of statement and clarity of expression, the most recent addition, entitled "Post mortem Methods," exhibits these virtues in an equal degree Upon general grounds it might be asserted that the conduct and interpretation of necropsies had already been completely exhausted by numerous excellent volumes dealing with this special branch of medicine, and that no niche on our bookshelf could be usefully filled by the present one Such, however, is not the case, and even a cursory glance through its pages shows that it goes a long way towards filling the gap the existence of which we have on several occasions indicated in these columns Up to the present time there has been no post mortem manual written by a pathologist who was at the same time a skilled and practical bacteriologist Consequently the importance of the application of bacteriological methods as a routine measure to every necropsy has hitherto never been sufficiently emphasised By his explicit instructions and constant references, Professor Beattie has done much to prevent the junior who follows his directions from seeking a haven of refuge in the diagnosis "status lymphaticus" before he has made a really exhaustive examination and drawn blank all the bacteriological covers

The book comprises four main parts In the first (Chapters I -III) we are rather surprised to see that Professor Beattie does not insist on the provision of a refrigerating chamber in connexion with the post mortem room of the hospital pathologist, particularly in view of the fact that bacteriological investigations play so important a part in post mortem work His reasons for preferring to work without gloves are sound, but we note that the operator, whose hands are reproduced in the photograph, having discarded gloves, sets a bad example by retaining his ring The methods recommended for opening the body and removing the organs are clearly those employed by the author himself, they are for the most part simple, and are set out with sufficiency of detail which renders them easily followed

The second section (Chapters IV -XI) deals with the macroscopical examination of the organs, and in this connexion it may be noted that weights and lengths are given in metric measurements, usually accompanied by their English equivalents Under each viscus the attention of the student is directed to the appearances of the naked eye lesions that may be present, and this section is particularly fruitful in those hints, suggestions, and explanations we have every reason to expect from a practical teacher of Professor Beattie's extensive experience

The next section deals with medico legal methods as applied chiefly to cases of suspected poisoning—no mention being made of sexual crimes or criminal abortions—and bacteriological methods to be employed when an experimental animal in the laboratory furnishes the cadaver In this part Cobbett and Graham Smith's instructions for examining birds are quoted *in extenso* Then follows a series of notes on the points to be elucidated in a number of specified conditions and diseases including the microscopical preparations to be made and the culture media to be inoculated when dealing with bacterial infections

The last section (an appendix) gives instructions for the preservation of the natural colours of organs intended for museum preparations by various methods, preference being expressed for those of Jones or Pick, Frost solution being used for the final mounting and the sealing up of museum jars The directions for the preparation of a few bacteriological culture media, which occupy the final pages, are so few and so scrappy that their omission would have improved rather than detracted from the value of the book as a whole

A full index completes a volume upon the production of which we offer the author our congratulations

---

LIBRARY TABLE

National Insurance Acts, Handbook for the Use of Approved Societies English edition London Wyman and Sons, Limited 1915 Pp 324 Price 1s —The Insurance Commissioners have issued in the form of a "Handbook for Approved Societies" a volume containing a considerable amount of information and advice, the object being to supply to the officers of the societies an official book of reference, information on procedure, and of guidance in applying the provisions of the Insurance Acts and of the regulations made under them The present issue is described as provisional only, and as revised to August, 1915 It applies only to England A more complete handbook is promised after the war, when our social organisation returns to normal courses In its tentative form the handbook contains more than 300 pages, and although the greater part of it deals with financial and administrative matters of intrinsic interest only to the societies for which it is compiled, medical men upon the panels, and particularly those entering upon panel work, will find a good deal of matter for their consideration in the paragraphs dealing with certification and sickness benefit

In the issuing of medical certificates many points of possible friction have made themselves felt, and the handbook appears to deal with these fairly and clearly, it should certainly assist the societies to carry out efficiently their duties in connexion with the distribution of sickness benefit. The fact that these duties are imposed upon the societies by the legislature and the necessity for every society in the interest of its funds and of its members to exercise care in supervising claims will be found to explain much that is contained in the handbook on the subject of certification In dealing with the subject of sick visiting it is pointed out, for example, in emphatic terms that the responsibility for determining whether a member is entitled to benefit rests not with the doctor who gives a medical certificate but with the society That is to say, that although the medical certificate constitutes a very important part of the evidence upon which the society has to base its decision it is not the only evidence that it may take into account in determining whether benefit is payable It will be observed however, that the societies are expressly warned that their visitors cannot be expected, and should not be allowed, to act as medical advisers, and that the proper means of obtaining further evidence on matters which require any medical knowledge is to refer the case to the doctor in attendance or to a medical referee

The paragraph relating to medical referees explains that, where a doubt exists as to whether sickness benefit should be paid after the medical certificates and the report of the sick visitor have been considered, the doctor in attendance may be able to help by supplying further particulars or otherwise but that in some cases of uncertainty as to a medical point the proper course will be to refer the matter to a medical referee, first informing the doctor in attendance and taking care that he is aware of the time and place of any proposed examination It is mentioned that power is given to the societies to require a member claiming benefit to submit himself to examination by a medical man appointed by the society and at the society's expense, and also that where in consequence of expenditure upon medical referees a deficiency occurs in its administration account, a society is allowed to carry a further limited sum to that account beyond the maximum amount ordinarily allowed by regulation

Other paragraphs to which attention may be drawn with regard to certification are those which explain the procedure with regard to certificates given by medical men not upon the panels who are in attendance upon insured persons The distinction between this form of practice, where the consent of the Insurance Committee has been obtained, and where it has not, is made clear, and it will be seen that from the point of view of the society, responsible as it is for the distribution of sickness benefit, the distinction is a necessary one In any case, whether a medical practitioner acquiesces or not in the course taken by the officials of an Approved Society with regard to a patient under his care, he will be better able to form an opinion on the subject by knowing how far the action of the society is justified by official advice and authority Therefore we recommend to all whom it may concern the purchase of this cheap handbook

War and Civilisation an Open Letter to a Swedish Professor By J M ROBERTSON, M.P London George Allen and Unwin, Limited Pp 160 Price 2s 6d net —In a series of trenchant chapters Mr Robertson gives a reply to a Swedish professor of economic and social science who undertook to set forth the real "rights and wrongs" of the present war Dr Steffen is perhaps hardly a worthy antagonist, inasmuch as he justifies his vaunted ten years' acquaintance with English habits of thought by isolated extracts from newspapers instead of by responsible pronouncements of statesmen, and finds the typical Englishman in some of Mr Galsworthy's most unrighteous and unlovable characterisations. Hence Mr Robertson has no serious difficulty in demolishing the superstructure built on this crumbling foundation Mr Robertson is himself one of those who "have seen in war the great negation of human progress, the destroyer of a hundred civilisations, the final failure of reason to regulate international life,' and he finds the German people deficient in that most essential thing, the knowledge of the way of working of the souls of nations and of free men His book will be read with pleasure for its keenness and fairness of thought and expression

JOURNALS

Quarterly Journal of Experimental Physiology Edited by E A. SCHÄFER, W D HALLIBURTON, C S SHERRINGTON, E H STARLING, and A. D WALLER. Vol IX, No 3 London Charles Griffin and Co, Limited 1915 Pp 199–279 Price 7s 6d —On the Mode of Origination of Labyrinthine and Cervical Tonic Reflexes and on their Part in the Reflex Reactions of the Decerebrate Preparation, by J S Breitoff This elaborate research was carried out in the Imperial University of Petrograd The author's conclusions alone and summary of his work extend to over three pages The experiments were made on decerebrate cats Antagonistic muscles—e.g, vasto-crureus and semitendinosus—were isolated and their actions simultaneously recorded The view is generally held that certain labyrinth tonic reflexes in certain positions of the head in space are produced directly under the continuous excitement of the labyrinthine receptors The author made the observation on antagonistic muscles that a weak peripheral stimulation evokes in them a tonic reflex in harmony with the posture then obtaining in the head The author's results, which are set out at length, do not lend themselves to a short summary, and one must refer those interested to the communication itself —On the Accumulation of Gas in the Tissues of the Frog as a Result of Prolonged Submersion in Water, by A. T Cameron and T I Brownlee The authors find that 1. Specimens of Rana pipiens immersed in Winnipeg tap-water during late winter and spring will live on the average 16 days The extreme periods observed were three and 52 days 2 The frogs remain perfectly normal for some time, but at a variable period before death ensues—usually several days—they commence to swell. The swelling in all cases is due to the absorption of water, and in *most* cases this is accompanied by retention of absorbed nitrogen, resulting in a degree of buoyancy which tends to keep the frogs at the surface of the water The authors discuss the probable causes of these phenomena —The Upper Limit of Temperature Compatible with Life in the Frog, by A T Cameron and T I Brownlee The authors had previously determined the lower limits of temperature compatible with life in the frog These were found to be $-1\ 25° \pm 0\ 15°$ C for R pipiens and for R. clamitans and R sphenocephala two to three tenths of a degree higher The minimal temperature was maintained for one hour Three series of experiments were made 1 On the intact animal immersed in water 2 On the intact animal in air saturated with water vapour and kept at a constant temperature 3 On exsected heart, muscle, and nerve, chiefly in late winter and spring specimens of R pipiens In the air experiments the highest temperature at which R. pipiens can maintain life indefinitely is about 18° C, while a temperature a degree or two higher proves fatal in a few days The cause of *somatic* death cannot be stated The heart was found functioning in numerous cases where somatic death has occurred The experiments in water indicate a similar limiting temperature The fatal effects are more rapid The experiments on exsected muscle show the important relationship between temperature and time The authors are unable to state the cause of death of muscle at moderate temperatures (25°–35° C) —The Proprioceptive Reflex of a Flexor Muscle, by Chuai Asayama Decerebrate cats were used It was found that (1) quick stretching of tibialis anticus, the chief flexor of the ankle-joint, by a sharp pull on its tendon elicits a reflex contraction of the muscle, it can also be obtained in the intact animal under narcosis, but is more marked in the decerebrate preparation, (2) the reaction is a proprioceptive reflex the only afferent nerve required being that belonging to the muscle itself, (3) the minimal amount of stretching required to evoke the reaction is very small, (4) the rate of stretching is important—a slow stretching, however ample, does not evoke the reflex, (5) the latent period is shorter than that for reflexes evoked from the muscle by other afferent channels, (6) when the reflex response of the muscle has been tired out for the ordinary "flexion reflex,' this proprioceptive stretch reflex persists unaffected by that fatigue, (7) strychnine increases the reflex

CLINICAL REPORT ON THE APPLICATIONS OF EUSOL

REPORT TO THE MEDICAL RESEARCH COMMITTEE

THE following concludes the Report to the Medical Research Committee, the first part of which appeared in our issue of last week The Report is signed on behalf of the Edinburgh Committee by the chairman Major James Hodsdon, President of the Royal College of Surgeons of Edinburgh

1 RECENT ACCIDENTAL WOUNDS

Cases tabulated from the surgical out patient department, Royal Infirmary, show that 86 per cent of recent wounds remained aseptic This result was obtained by means of free application of eusol before dressing A dressing of gauze soaked in eusol was applied over the wound after stitching and in a few cases this was covered with jaconet As a rule, however, the dry dressing was sufficient to keep the wound aseptic It has been noted that in the treatment of small wounds where there is every probability of sepsis, it is a good plan to apply a eusol soak for the first 24 hours—i e, before stitching, and thereafter a dry dressing This renders drainage unnecessary Of the cases that became septic (10 per cent) this was, as a rule, due to the fact that the patient did not return when directed or interfered with the dressing One or two of the cases became slightly septic during treatment This occurred, however, before the value of preliminary treatment in certain cases with soaks had been realised

Mr Jardine and Lieutenant Cameron's Case

TABLE A, CASE 47 —Case of street accident The patient had been knocked down by a tramcar and the street dirt had been ground into the interior of a scalp wound 4½ inches long The tissues were quite black and it was impossible to remove the dirt by sponging The gross dirt was cut away and the wound and surrounding parts were thoroughly sponged with eusol, the wound was then packed with gauze impregnated with eusol and a eusol soak was applied over the surface The wound was not stitched as it was so dirty Twenty four hours later when the packing was removed the wound was clean enough for partial stitching The slight discharge of pus entirely ceased in 5 days, and 9 days later patient was discharged cured.

Captain Stuart's Case

TABLE B, CASE 1 —Motor car accident, overturning on hard country road Large antero-posterior scalp wound from anterior margin of hair almost to external occipital protuberance, much undermining of flaps, extending on one side to base of mastoid part of pericranium being torn away, with exposure of bone There was a second scalp wound about 4 inches long on the other side of the scalp, also much undermined There was much infiltration of the deep surface of the scalp flaps and of the pericranium with road dust Wounds were thoroughly washed out with eusol and dirty tags were cut away, but it was impossible to remove the dirt completely Gauze swabs soaked in eusol were laid under the scalp flaps and left there while the scalp was being shaved and painted with iodine, no iodine was put on the wound edges nor into the wound The smaller wound was closed without drainage, the larger one was completely closed but a small tube was introduced into the cavity through a stab opening above the ear Both wounds healed by first intention without a sign of sepsis

TABLE B, CASE 2 —Same accident as B 1 Antero-posterior wound of scalp beginning close above the right eye, passing through the eyebrow, up the forehead and backwards to rather beyond the level of the external occipital protuberance The lateral flap of the scalp had been raised, as in the previous case down to the mastoid There was another long wound on the left side of the scalp with undermined edges, and a small wound farther back Pericranium was exposed and parts of it torn away There was not much road dirt in the wounds The case was dealt with in precisely the same way as B, 1 All the wounds were stitched up completely, but small pieces of tubing were introduced through stab openings into the large wound All healed by first intention with the exception of a small circumscribed area in front of the ear, a small abscess formed and was incised

Captain Stiles's Case

TABLE A, CASE 9 *Septic burn of thorax* —An extensive superficial burn of the thorax of 2 weeks duration was dressed twice daily with eusol On admission the ulcer was dirty, covered with large greyish yellow sloughs, and showed no sign of healing Within 5 days the sloughs had entirely separated, leaving a healthy granulating surface dotted here and there with islands of epithelium The granulations after another 2 days became so vascular that the eusol dressings were stopped and boracic substituted The child was discharged 7 days after admission and treated as an out patient. There is no doubt that the eusol cleaned up and stimulated the burn with greater rapidity than any other antiseptic used here (Royal Hospital for Sick Children Edinburgh)

Mr J M Graham's Cases

TABLE A, CASE 94 *Partial avulsion of the scalp treated by eusol* —The patient a boy aged 4 was knocked over by a motor car on Nov 29th, 1915 He was dragged for a considerable distance, and was brought into hospital unconscious It was then found that the scalp was cut to the bone transversely from ear to ear and the posterior portion was completely separated from the cranium Much dirt was ground into the edges of the wound into the under surface of the flap, and also into the surface of the bones of the skull which were exposed Three hours after the injury the patient had recovered consciousness and under a general anæsthetic the scalp and exposed parts were cleansed with eusol Portions of dirt were removed with forceps and by clipping the tissues with scissors The parts were sponged with gauze soaked in eusol, and the latter was freely used to wash out the recesses of the wound After thorough cleansing the wound was completely stitched up after the insertion of two small drainage-tubes at dependent points The wound healed by first intention

TABLE A, CASE 95 *Severe laceration of right arm requiring amputation* —The patient a boy aged 15 fell off a railway engine a wheel passing over his right arm He was seen in hospital four hours after his injury, a tourniquet which was applied at the time of the accident still being in position The skin muscles and other tissues about the elbow were much torn, and the raw surfaces were ingrained with dirt, the lower third of the humerus was comminuted and the elbow joint dislocated The skin was completely stripped off the muscles as far as the shoulder joint An anæsthetic was administered and a circular amputation performed through the middle of the upper arm, the skin and the wound having first been thoroughly washed with swabs soaked in eusol The stump healed by first intention

TABLE A, CASE 96 —The patient was a man aged 60 Both hands were crushed by the wheels of a light engine On admission he was very collapsed and was suffering from severe shock The left hand was practically reduced to pulp and was only connected to the arm by a confused mass of torn tendons The right hand was severely damaged and the thumb was missing All the fingers were crushed and metacarpal bones broken, except that of the little finger Part of the skin of the palm was intact The following treatment was carried out four hours after the accident Right hand Careful cleansing with eusol, damaged parts removed, tendons stitched over the carpus and flap sutured in position The base of the thumb and entire little finger were saved Left hand Amputation was necessary above the wrist The parts were thoroughly irrigated with eusol The raw surfaces were black with dirt Saline enemata were administered After progress The right hand healed by first intention with the exception of a little necrosis at the line of suture In the left hand a considerable slough formed at the apex of the dorsal flap owing to lack of vitality in the skin This was associated with slight sepsis which disappeared with removal of the slough.

TABLE A, CASE 97 *Compound comminuted fracture of the elbow region* —The patient was a man aged 69, who was admitted 1¾ hours after being knocked down by a passing goods trains, four wagons passing over his elbow On *admission there was considerable shock, subnormal temperature* (95° F) One large wound, 3 in long and 2 in broad was situated in front of and above the head of the radius There were several smaller wounds and much general bruising of the arm The raw surface was ingrained with dirt There was a compound, much comminuted fracture of the lower end of the humerus As the radial pulse was good *and there was no evidence of destruction of nerves,* it was decided to try to save the arm The wound was thoroughly irrigated with eusol and packed with swabs wrung out of eusol The arm was laid on a pillow with the intention of securing ankylosis The radiogram showed a comminuted fracture of all the bones *entering into the elbow joint* After progress A large amount of muscle and some skin *sloughed during the first week* A slight amount of suppuration was present and numerous fragments of bone were removed The patient is still under treatment having just had a large sequestrum removed On the whole the result has been very satisfactory, as the patient has now considerable power of *movement at the elbow joint Considering* the severe nature of the injury, it was doubtful at the time *whether the arm could* be saved at all

2 WOUNDS ALREADY SEPTIC

Where *septic* processes are already present in the wound the treatment has usually been carried out by means of syringing and soaks or baths The aim is in the first *place to* eliminate sepsis If it be necessary for this purpose to apply eusol every four hours a drainage tube should be inserted and so arranged *that* it can be used as a channel for irrigating the wound with a minimum disturbance *of* the dressings In a septic cavity the antiseptic, warmed to body temperature, should be brought into contact with all the recesses and applied as freely as *possible to* the whole of the infected area Hypochlorous acid forms a compound with the albuminous substances in the exudate and is thereby decomposed, but the compound is itself an antiseptic To secure the elimination of sepsis it is important, therefore, to flush the cavity freely

The eusol brings about separation of the sloughs and formation of a covering of granulation tissue over the raw surface A *minimal* amount of discharge remains consisting of serous fluid, and this can be absorbed by a loose packing of gauze soaked in eusol, *the wound is thereby kept sufficiently* dry while healing proceeds Where a tube is combined with the gauze the tube should be removed once and the gauze *at* least twice in 24 hours in the earlier stages of the treatment

It has been found beneficial in some cases to change the treatment after granulations have formed Eusol may be alternated with another form *of* dressing, or it may be discontinued when the sepsis is under control Any tendency to exuberant growth of granulations and delay in healing can be counteracted in various ways indicated in the notes on the cases

While the cases recorded are sufficient to indicate the general principles involved in the treatment of wounds by eusol, further experience is required to determine the methods appropriate to wounds of a special or unusual character

Major Hodsdon and Mr Wood's Cases

TABLE B CASE 25 —A sailor had both legs injured by shell fire and amputation of the right was performed When the patient reached Edinburgh Royal Infirmary the flaps covering the stump had become gangrenous and sloughing, there was a foul discharge Washing and dry dressing with eusol for 13 days cleaned up the surface and skin grafting was successfully carried out

In the following four cases the patients were wounded on Sept 25th and admitted to the Royal Infirmary on *Oct 5th*

TABLE B, CASE 26 —A very severe case of compound fracture of the arm, with splintering of the lower third of *the humerus and upper third of the radius* and *ulna* Copious purulent discharge After the wound had been opened up to allow free drainage and application of eusol, the arm healed rapidly and the patient's general condition improved markedly The discharge had practically ceased in 19 days

TABLE B, CASE 27 —This was a case of compound fracture of both bones of the forearm. There were two large gaping wounds with a copious offensive discharge The lower part *of the ulna was completely shattered The wound here was* treated by syringing and wet dressing once daily In 5 days the wound was much cleaner, and in 4 weeks both wounds were in the condition of a healthy sore The wound cleaned up remarkably well

TABLE B CASE 28 —This was a case of bullet wound in the palm of the right hand It was very dirty and discharging pus freely, the hand was swollen and inflamed It was treated by syringing and wet dressing once daily, and in 9 days the wound was almost clean Eusol cleaned up *this case and reduced the amount of discharge* very quickly Numerous splinters of shrapnel had to be removed Apart from this the wound was completely healed in a fortnight

TABLE B, *CASE 29 —This was a case of compound fracture* of left femur The wound through the thigh was very septic and *foul smelling* A large cavity was present in connexion with the exit wound The wound was syringed and wet dressed twice daily There was distinct improvement in 6 days Nine days after this a large sequestrum was removed, and 13 days later a piece of shrapnel was removed and another piece 5 days later The wound healed up rapidly and the bones became quite firm

Major Wallace and Dr Bennet Clark's Cases

TABLE B *CASE 48 —This* was a case of shrapnel wound of the upper arm There was a sinus about 2 inches long, which was not healing It was 17 days old The sinus was treated for 14 days with eusol *soaks* every 4 hours At the end of this time treatment was changed to syringing and dry dressing twice daily Under the latter treatment it healed in 6 days This case exemplifies the fact that the mode of application of eusol is highly important, and that it must be directly applied to the infected surface

TABLE B CASE 52 —This was a case of large superficial lacerated wound of the forearm covered with sloughs, discharging profusely The pus was thick and foul smelling It was treated with *eusol* soaks, 4-hourly, and was sufficiently clean for skin grafting in 8 days, it was completely healed a fortnight later This was considered a very successful case

TABLE B, CASE 43 —This was a case of superficial shrapnel wound of 48 days' standing, it was situated in the shoulder and was very foul Eusol soaks applied every four hours cleaned the wound and it was healing rapidly after 10 days

Dr R W Johnston's Case

TABLE B CASE 57 —This was a case of compound fracture of the femur There had been six operations during a period of 8 months At the time when eusol treatment was commenced there were two septic sinuses each 4 inches deep leading down to the femur, and it was suspected at first that dead bone was present The sinuses were irrigated with eusol twice daily and lightly packed with worsted soaked in eusol The sinuses healed in 6 weeks The record continues "In view of the long history of sepsis this is a remarkably satisfactory result Patient was discharged for light duty"

Captain J W Stuart and Dr Andrew Rutherford's Case

TABLE B CASE 40 —This was a case of shrapnel wound of the foot. Amputation through the thigh was done because of rapidly spreading gangrene When the patient reached the Deaconess Hospital the stitches had burst, the flaps having given way and receded for a considerable distance, leaving the stump of the bone exposed The surface of the flaps was bathed in pus and emitted a fœtid odour It was treated with soaks twice daily and eusol was poured into the dressing every 4 hours by a tube which had been inserted for the purpose The surface of the wound became healthy and the end of the bone became covered with healthy granulations It was originally intended to remove some of the bone and make new flaps, but this was found unnecessary

Note by Lieutenant Colonel Caird

"Military cases Gunshot and shrapnel wounds Fifteen cases, admitted 7 to 10 days after receipt of injury, all septic and suppurating progressed in a satisfactory manner None had rise of pulse or temperature and all healed well, although three were very slow One case proved fatal where an operation to remove a small sequestrum from the tibia was followed by an acute septicæmia and endocarditis which carried off the patient on the eighteenth day" The post-mortem examination showed chronic and acute endocarditis of the aortic valve Septic thrombosis of the femoral vein, and infarction of the spleen

"One case, a disarticulation at the knee joint with retracted flaps and protruding extremity of femur, was admitted 17 days after operation The wound was sloughy, temperature 102°, pulse 120 Eusol dressing applied August 10th Temperature normal, wound granulating and pulse normal August 20th Healing thereafter promoted by change of dressing and epithelial grafting"

Note by Captain Stiles

"I may say that I have used eusol in many other cases besides those referred to in the tables The conclusions I have come to are that eusol is the most efficient antiseptic we possess in the treatment of the lacerated and contused wounds and compound fractures such as are met with in military practice It brings about the rapid separation of the sloughs and healthy granulations form more rapidly than under the use of any other antiseptic, its continued use causes an excessive growth of very vascular granulations so that bleeding from them is more severe than usual During the later stages of the treatment, therefore it is advisable to substitute either hypertonic salt solution or boracic for the eusol"

Captain A A Scott Skirving

Writes that he has employed eusol in several hundred cases in Craigleith and Bangour Military Hospitals and in civil practice His experience has been such as to lead him to order it as a routine treatment in every case where an open wound existed, and the results obtained have justified its use

Note by Captain Beesly, Surgeon Specialist, the Military Hospital, Edinburgh

"The only cases in which there has been a suitable opportunity for testing thoroughly the value of eusol in the Military Hospital Edinburgh, have been those of chronic localised sepsis of bones usually associated with cavities and sequestra Such cases have been plentiful, and the eight months which have elapsed since the treatment described below was first begun have allowed time for a definite opinion to be formed regarding the advantages possessed by eusol

Many of the patients under consideration had had four or five previous operations, and, as far as could be made out the recurrences were due to healing of the superficial soft structures before the underlying bone had healed In view of this the following method was adopted The area dealt with was widely opened up the sequestra removed and the cavity or cavities bevelled away as flat as the security to the shaft of the bone permitted Thereafter the area was kept wide open and the cavity down to the bone, lined with a sheet of perforated green protective, was packed with iodoform gauze to keep it fresh and to control the oozing This dressing was not changed for three days

This primary iodoform dressing was found more satisfactory than gauze soaked in eusol as the latter required to be changed daily The subsequent dressings carried out daily comprised washing the area thoroughly with warm eusol (0 5 per cent hypochlorous acid) and packing it in the same manner as before but with the gauze soaked in eusol By this method the area was kept permanently clean the serous discharge reduced to a minimum and the granulation tissue never became vegetative

It was noticed that eusol could be applied continuously in the prolonged treatment necessary for the closure of these large open wounds whereas other applications could not be so used and required to be alternated with each other

A distinct advantage of the eusol dressing is the marked reduction of the serous exudate This allows the deeper parts of the wound to be lightly packed and the superficial area to be firmly packed, there being no question as to obstructing the outflow of the discharge In this way the superficial tissues are kept widely separated, and the deep seated wound in the bone can be observed healing The very slight amount of serous discharge which occurs readily passes through the perforated green protective and is absorbed by the eusol gauze, which, however, never becomes sodden, and in no case thus treated was there trouble from hæmorrhage or overgrowth of granulations

There has been little opportunity of testing the value of eusol in acute suppurative cases, but in a few patients with gangrenous appendicitis it was noted that the period of drainage and pus discharge was much curtailed when the area was thoroughly cleansed with eusol In three such cases the tubes were removed upon the third day, and all discharge had ceased by the sixth day These patients left hospital completely healed in 21 days"

3 SEROUS AND SYNOVIAL CAVITIES

Note by Lieutenant Colonel Caird

"Cases of extravasation of urine and gangrenous appendicitis with fæcal fistula, temperature was reduced and sepsis controlled on being treated with eusol"

Mr W Q Wood's Case

TABLE A, CASE 89 —In this case—one of perforated gangrenous appendix—the patient was very collapsed on admission, with a temperature of 100° F and a pulse of 132 She had been ill for 5 days Immediate operation Patient had general peritonitis with foul smelling pus and a quantity of free gas throughout the lower part of the abdomen The abdomen was freely douched out with eusol The patient made an uninterrupted recovery This case demonstrates the fact that eusol can be employed in the peritoneal cavity with the greatest safety

Note by Captain Stiles

"In the Hospital for Sick Children the method of treatment in cases of appendicitis is to irrigate the drainage tracks freely twice daily two days after the operation Formerly peroxide of hydrogen was used for this purpose better results, however, have been obtained by application of eusol, and the patients are discharged about a week earlier than was previously the case"

Note by Captain Stuart

"*Appendix cases* —I have employed eusol during the last seven months in 14 cases of acute appendicitis, where the appendix was gangrenous and perforated, with offensive pus round it In all cases the peritoneal cavity was necessarily opened the appendix was removed and a rubber tube left in the lateral wound while a glass tube was introduced to the bottom of the pelvis through a suprapubic opening The glass tube was almost invariably removed on the second or third day, and the rubber tube gradually shortened till healing occurred In the early cases no eusol was employed at the operation The cases in question all behaved in very much the same way There was a fairly profuse very offensive discharge from the lateral tube and on about the fourth or fifth day the larger rubber tube having been taken out a small one was passed down to the bottom of the wound and about half a pint of eusol syringed down the tube, so as to well out by the side of it the larger tube being again replaced In a few cases this was done twice daily for two or three days and then once daily in most of the cases only one daily dressing was performed from the first As a rule, in two to four days the smell had practically disappeared, the infection disappearing with a rapidity which I have not seen under any other treatment When the sinus became practically aseptic the use of eusol was stopped, otherwise healing was delayed

In the last two or three cases I have at the operation swabbed out the region of the appendix with slightly warmed and therefore slightly dilute eusol and poured it through the lateral wound down into the pelvis This eusol was sucked out again through the suprapubic tube at the close of the operation I have not yet done this often enough to form an opinion regarding it but in these very few cases I think that the discharge afterwards was less profuse and less offensive though asepsis was not secured

Note by Captain Stiles

"*Empyema* —In my experience empyemas do well if they are opened early and if a large enough opening is made to enable the fibrinous masses to be removed If this is done there is usually no need to keep the tube in more than a few days The main point, however, in the after treatment is the prevention of mixed infection This is best effected by the application of a large eusol dressing, which should be changed daily And this leads me to say that I have met with no cases in which any irritation of the skin has resulted While I have not thought it necessary to douche out the pleural cavity at the operation I have found that in old standing fœtid empyemas the best results are to be got by free irrigation with eusol, as by this means the fœtor is more rapidly controlled than by the use of any other antiseptic, and the fever is at the same time more effectively reduced."

Major Hodsdon's Case

"*Streptococcal synovitis* —Patient was wounded in the left leg in Gallipoli on Oct 25th. A bullet was removed from the leg on Nov 8th on board a hospital ship When he was admitted into the Royal Infirmary on Nov 16th there were three large suppurating wounds in the calf. An abscess over the internal malleolus was opened on Nov 24th. On the 26th the temperature was 102°–103° F , pulse 120–125 There was effusion into the knee joint The joint was aspirated on the following day , sero-purulent fluid (which gave a pure culture of streptococci) was drawn off and 2 oz. of eusol injected into the joint. The knee improved during the next 24 hours On Nov 30th the temperature was 102° , pulse 112–124 , the joint tightly distended and very tender to touch. The patient was extremely ill and toxic in appearance Under general anæsthesia the effusion, which was now purulent (and still gave a pure culture of streptococci), was removed by aspiration, the joint washed out with eusol and freely moved until the fluid which returned was clear , finally the synovial cavity was distended with eusol, the puncture being closed by a clip to prevent escape of the antiseptic The following day the general and local conditions showed marked improvement and the joint was painless to touch. The temperature however, remained at 101°–102° and the pulse at 112–118 until Dec. 3rd, when a collection of pus was evacuated from the lower third of the thigh. Two days later the temperature was normal, the pulse 108 the joint condition had completely subsided, and passive movement was painless "

4 Mucous Surfaces

In acutely inflamed mucous surfaces the application of eusol may produce pain and discomfort On the other hand, in chronic inflammation even the full strength can be easily borne In the tables only a few cases are recorded of application to mucous surfaces In cases of cystitis or colitis the eusol for the first application may be diluted with warm normal saline to 1 in 10, but it will be found that the patient can soon tolerate a much greater concentration

Lieutenant Colonel Caird's Case

"Suprapubic removal of extensive papillomata of bladder , great hæmaturia, foul urine On the day after operation the temperature rose to 100° F the pulse to 120 and the following day the patient looked very ill The bladder was washed out with eusol, and at night the temperature was normal and the pulse had fallen to 112 Subsequent progress satisfactory '

5 Inflammatory Lesions.

(*a*) *Cellulitis*

Captain Stiles's Case

TABLE A CASE 36 —The patient was a nurse who had a whitlow of the thumb She was very ill, with a temperature of 104° F and a suppurative condition extending along the long flexor of the thumb into the forearm There was marked œdema of the thumb with swelling and tenderness of the axillary glands A free incision was made in the palm and another longer one in the forearm down on to the flexor longus pollicis tendon. The limb was then placed in a eusol bath for two hours twice daily, and in the intervals a boric bath was substituted The fever disappeared in a few days, the œdema quickly subsided, and the wound rapidly became covered with healthy granulations

(*b*) *Abscess* (See Table A, Cases 25 and 26)

(*c*) *Amputations through Septic Tissues*

Note by Captain Stiles

"In performing these amputations I have been gratified to find that by douching the flaps very freely with eusol and applying eusol dressings very frequently the healing has been almost as rapid as in an aseptic amputation "

While the report does not include cases of amputation for "gas gangrene" the committee may be permitted to refer to the results obtained by Captain John Fraser in the field, an account of which was published in the *British Medical Journal* on Oct 9th, 1915 He showed that by the application of eusol he was enabled to amputate successfully through infected tissue

(*d*) *Arthritis with Mixed Infection, Amputation*

Captain Stiles's Cases

TABLE A, CASE 24 —"This was a case of very advanced hip-joint disease with extensive involvement of the acetabulum and septic sinuses At the operation the sinuses were dissected away as far as possible, and after thoroughly irrigating the wound with eusol, eupad was freely applied to the curetted acetabulum and to the unhealthy tissues round about the sinuses The child's condition improved very quickly, and I am satisfied that the healing process was more rapid than I had been accustomed to see in similar cases which had not been treated with eusol

The beneficial action of eusol was even more strikingly shown in another amputation of the hip-joint in a child who had suffered from severe osteomyelitis of the shaft of the femur with secondary involvement of the hip-joint The flaps healed practically by first intention and the child who was almost moribund at the time, put on weight with great rapidity, and is now, eight weeks after the operation in robust health No doubt the removal of the septic area accounted for the child's recovery, but the eusol, in my opinion, certainly added greatly to the rapidity and completeness of the convalescence '

(*e*) *Tuberculosis of Bones*

Note by Captain Stiles

"After removing the tuberculous focus it has been my practice recently to apply eupad freely to the cavity which has been left, using it as a substitute for sublimated iodoform bismuth paste I have also applied it freely to the curetted acetabulum after excising the hip for tuberculous disease I have then stitched the muscles over the trochanter and closed the wound without drainage The eupad did not appear to produce any pain or irritation Healing by first intention resulted but the same has occurred after the application of sublimated iodoform bismuth paste '

6 Skin Infection

Dr J W Crerar's Case

"Case of coccogenic sycosis (Unna) treated with eupad On Sept 20th Lieutenant S presented himself with extensive pustular eruption of chin, cheeks and neck, the pustules closely aggregated on chin, especially just below the lower lip discrete on the cheeks and neck. A paste of eupad and water was thoroughly rubbed into the whole infected area and left in contact for 15 minutes This was washed off and an indifferent bland ointment was ordered On Sept 22nd (two days later) close examination with a lens revealed only 3 small pustules on the neck To these a paste of eupad was applied On the 24th (two days later) 3 fresh pustules were seen and similarly treated , no others to be seen. On the 27th (three days later) careful examination failed to reveal a single pustule Cheeks and neck were normal and the only sign of the condition was slight (non pustular) excoriation below the lower lip Treatment completely cured the condition within one week Cultures from a pustule gave a growth of staphylococcus pyogenes aureus For application of eupad in this manner it is advisable to place a pad of gauze moistened with solution of sodium hyposulphite over the mouth and nose to prevent respiratory irritation from the hypochlorous acid gas '

7 RECTAL OPERATION

Major Hodsdon and Mr Wood s Case

TABLE A, CASE 5 — 'A feeble man aged 68 Colostomy on August 15th, the lower part of the rectum and anal canal excised under spinal anæsthesia on August 26th, wound packed with iodoform gauze On the evening of the 26th the temperature was 99° F and pulse 120 On the morning of the 27th the wound was sloughy and the discharge very fœtid, temperature 98 4°, pulse 124 The wound was syringed out with eusol and packed with gauze dusted with eupad That night the pulse rate fell to 88 and subsequently never exceeded 96 The fœtor rapidly diminished, the wound was granulating on the third day and healing satisfactorily The eupad packing was discontinued on August 30th, the syringing once daily with eusol was continued until Sept 20th "

Captain Stiles s Case

TABLE A, CASE 6 —"The wound was that of a large carcinoma of the rectum just within reach of the finger A preliminary colostomy was first performed and the rectum excised a few weeks later by the sacral route The wound healed by first intention, and the drainage openings were completely closed at the end of the fifth week. I attribute the absence of fever after the operation, the general well being of the patient, and the rapid healing mainly to the closure of the end of the divided bowel, but partly also to the daily irrigation with eusol of the large cavity left in the pelvis Experience of rectal cases suggests the value of eusol in inoperable cases of carcinoma of the rectum after colostomy, also as a vaginal douche in inoperable cases of carcinoma of the cervix uteri and other septic conditions about the female genital passages

Operation for Carcinoma of the Mamma

Lieutenant Colonel Caird s Case

"Markedly septic case with foul odour Huge fungating carcinoma of the mamma Removal complete with glands On the seventh day the discharge became very offensive and penetrating, eusol dressings were applied twice daily On the second dressing all odour had gone, the discharge diminished and had practically ceased at the end of a week Patient up on seventh day Wound stationary for a time, a change to boric acid and red lotion at once hastened healing Throughout the patient had no elevation of temperature or rise of pulse "

GENERAL CONCLUSION

Further clinical experience of eusol in a great variety of cases has proved it to be a non toxic, non irritating, and efficient antiseptic Nothing in this experience has been more striking than the fact that while it is highly destructive to bacteria it is non toxic to the tissues In eusol free hypochlorous acid is the most essential ingredient, but there is present also a sufficient quantity of biborate of calcium to give the solution a reaction alkaline to litmus This feebly alkaline solution can be introduced into wounds or serous cavities with perfect safety It can even be left in such cavities in quantity without any harmful effect In lacerated and contused wounds, and in compound fractures, such as are met with in military practice, it is the most efficient antiseptic we possess

It is most efficacious during the period of what might be termed progressive sepsis Some surgeons have emphasised the benefit of modifying the treatment when sepsis is subsiding or has ceased. The granulations form after a period of two to three days, and rapidly cover the surface of the wound Any tendency to superabundant growth of granulations and consequent delay in healing can be counteracted either by so applying the eusol that the serous discharge is reduced to a minimum and the wound is kept dry, or by discontinuing eusol and using other dressings appropriate for healing wounds In any event the sepsis is by this stage completely under control

The freedom which can be exercised in the application of eusol, and the rapid action which it has in arresting the sepsis and discharge of an infected wound, led to experiments on the effect of eusol on the blood Following on this eusol was employed in the treatment of general septic toxæmia by intravenous injection

This method was first made use of by Lorrain Smith, Ritchie and Rettie,[1] in a case of grave puerperal septicæmia, and the result was the recovery of the patient They have applied the treatment in other similar conditions In several cases toxæmia has been successfully overcome, and although such a result has not been uniformly attained, the safety of the method justifies its being applied in the diseases referred to in their preliminary communication Intravenous injection has also been applied with success by Captain Fraser and Captain Bates in cases of acute toxæmia secondary to gas gangrene [2]

Further research is now being carried out on the development of the subject foreshadowed by these investigations

APPENDIX

Some practical considerations remain Hypochlorous acid is an extremely active bleaching agent, and it should therefore not be brought into contact with coloured fabrics Further, if cloth is kept in the solution for some time its fibres are made brittle from destruction of the texture Any towels, &c, which become wetted by the lotion should be forthwith rinsed in a large quantity of water to remove the acid as rapidly as may be It also is corrosive to metals, instruments, needles, &c, should be carefully treated, else they will rust

The lotion is exceedingly inexpensive The ingredients are procurable everywhere at a slight cost, and the preparation is a very simple process At the present time especially it will be found that the introduction of eusol will effect economy in the outlay for the treatment of septic wounds, a point of considerable importance, since phenol and its derivatives are becoming increasing difficult to procure

Finally, it may be useful to set forth the details for preparing the antiseptic Eupad powder is composed of equal weights of *boric acid and bleaching powder* The boric acid *is in sufficient excess to set free the hypochlorous acid in the solution* The bleaching powder should be dry and should contain 28 to 30 per cent available chlorine

The solution eusol is prepared as follows Add to 1 litre of water 25 grammes of the powder, shake well and allow it to stand an hour, then filter The clear solution is eusol, and contains about 0 5 per cent hydrochlorous acid If the bleaching powder is old or not up to the strength given above, use a larger quantity of the powder

A rough and ready method of preparation is to add ½ oz. of the mixed powder to 1 pint of water, stir or shake and allow the sediment to settle

In cold weather the solution will keep its strength for three weeks, in hot summer weather it loses its strength more rapidly, and should not be kept more than one week It keeps best in bottles of coloured glass in a dark cupboard

For use as a lotion the solution must be warmed This may be done by placing the bottle in a basin of hot water, or the solution may be made double strength (50 grammes to the litre) and diluted with an equal volume of hot water The double strength solution will not keep its value for more than two days

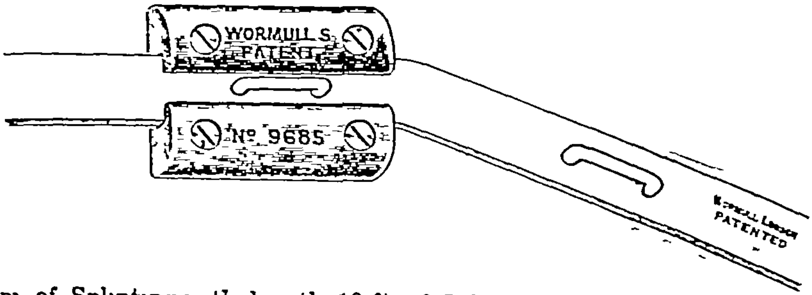
THE

SYSTEM OF ALUMINIUM SPLINTING

Devised by Sir FREDERICK TREVES, Bart, G.C.V.O., C.B., &c.

(Referred to by C MAX PAGE, M S, F R C S, Capt, R.A.M C (S R), in his article in the *British Medical Journal* of May 15th, as "Aluminium Skeleton Splints")



By this system of Splinting with length 10 ft of Side Bar weighing 1 lb., and 10 ft Strip weighing 5 ozs, a Splint for almost any part of the body can be made A number of smaller Splints may be produced with the same quantity of material

This material can be sterilized and used over and over again without impairing its strength

FULL PARTICULARS FROM PATENTEE—

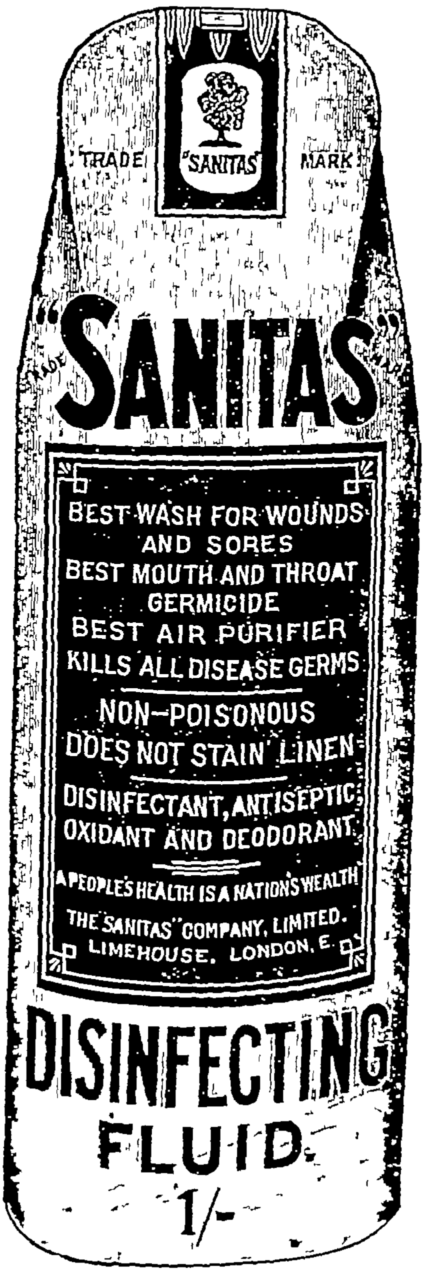
"SANITAS"



TRADE "SANITAS" MARK
"SANITAS"
BEST WASH FOR WOUNDS AND SORES
BEST MOUTH AND THROAT GERMICIDE
BEST AIR PURIFIER
KILLS ALL DISEASE GERMS
NON-POISONOUS
DOES NOT STAIN LINEN
DISINFECTANT, ANTISEPTIC, OXIDANT AND DEODORANT
A PEOPLE'S HEALTH IS A NATION'S WEALTH
THE "SANITAS" COMPANY, LIMITED. LIMEHOUSE, LONDON, E.
DISINFECTING FLUID
1/-

INDISPENSABLE IN SICK ROOMS AND NURSING WARDS.

1. Protects from all Infectious Diseases, and is the best WASH for WOUNDS, SORES, and TENDER FEET
2. Is a PERFECT MOUTH WASH and is an excellent dressing in cases of PUTRID and FOUL ULCERS, also as a PREVENTIVE of Pyorrhœa, Rigg's Disease, and Septic Poisoning caused by BAD TEETH
3. For Injection (after proper dilution) in ULCERATIO and MALIGNANT DISEASES of the UTERUS
4. As a MOUTH WASH in CANCER of the MOUTH and TONGUE
5. Makes the MOST EFFECTIVE GERM KILLING GARGLE, preventing and arresting SORE THROAT
6. "SANITAS FLUID" is NON POISONOUS, PLEASANT, DOES NOT STAIN LINEN, acts as an Oxygenating AIR PURIFIER (used as a spray), and is the onl Disinfectant fully qualified for TOILET USE

Sold in 6d and 1/- Bottles, and 5/- per gallon by all Chemists

For ANTISEPTIC SURGERY use "Sanitas-SYPOL."

Forms a clear solution with water, and is an improvement on German "Lysol"

Physical Treatment for Disabled Soldiers

A QUITE serious problem which faces not merely the Army Medical Service, but the medical profession as a whole, is the relief of the injuries of warfare Where these are actual wounds treatment is never considered complete until the wound has healed and the continuity of surface re established It seems sometimes as though too much thought is concentrated on the surface appearance of recovery, while the efficiency of the man as a worker depends rather on the function of the underlying structures of the locomotor system, the joints and the muscles and tendons which move them. Where limbs are lost entirely, careful and ingenious measures have been applied to replace them and to perfect the substitutes Where, however, stiffness and pain and disability remain in limbs which have been saved, men have been, and are still being, discharged from the services before these disabilities are entirely removed We published last week a proposal[1] for the combined physical treatment of wounded and disabled soldiers which may prove to be the beginning of a great national scheme The committee from whom this proposal emanates was appointed more than a year ago by the Balneological Section of the Royal Society of Medicine, and has had the advantage of the coöperation of the President of the Royal College of Physicians and of the Deputy Director General of the Army Medical Service We see here the beginning of a movement that may have far reaching effects

NAAMAN despised the use of water as a healing agent, and we to day, in this country, seem sometimes to have a similar attitude, probably because the application of simple physical remedies to the cure of disease has been so often associated with conspicuous charlatanry Yet it is droll that, in the country where water is so largely used as an agent of personal cleanliness, its other properties should be disregarded. Outside this country the medicinal value of baths is hardly a matter of dispute Pfafers alone—to name an instance—commands 100,000 such visitors annually And the revival of the British spas now that the European ones are less accessible testifies to the existence of the need for hydrotherapy and its allied physical methods It is an old observation that stiff limbs otherwise intractable, can often be mobilised with comparative ease and without pain after preparation by moist heat The work at the Grand Palais in Paris, which is summarised in the report of the committee of the Balneological Section of the Royal Society of Medicine, is now offering a concrete example of the application of such methods on a large scale to the special needs of the moment, and the results should be a matter for careful scrutiny The committee which has studied this work is of opinion that an opportunity should be given in this country for an effective scheme of similar treatment in an institution devoted to the purpose It is now for the medical profession as a whole to consider whether the claims made out for the movement by its sponsors are sufficiently well founded to warrant such a course We think they are

The details of such a scheme are of secondary importance There need be no slavish imitation of the Grand Palais The four component methods of a combined physical treatment are (1) baths, warm or cold, (2) the application of dry heat, whether radiant or hot air, (3) massage or mechanical mobilisation, (4) electricity In the application of each of these much variety is possible Under the first heading the "whirl" bath has been found of special value in Paris It is probable that just as under the stimulus of competitive manufacture, improvements in artificial limbs and their application are, we learn, being evolved, so where the opportunity for the comparison of various bathing methods is offered a natural evolution of efficiency would occur There may, for instance, be some difference of opinion as to the relative value of active and passive movements, and whether the latter can best be applied by a human agent or by apparatus of the Zander type The Zander apparatus is unfamiliar in this country, but where it has been scientifically applied, as at the Edgar Allen Institute at Sheffield, it commands a considerable measure of support Some who have seen these institutes at Stockholm and elsewhere have found them full of elderly individuals who take too much food and too little exercise, and for whom the Zander treatment provided an agreeable form of forced labour The principal advantages of the Zander apparatus over the passive movements by a human agent seem to lie in the economy of personnel, the accuracy of dosage as regards time and number of movements, the exact amount of resistance applied which can only be accurately measured and graded by an apparatus It thus would make for greater efficiency in so far as the movements prescribed by the experienced operator could be the more accurately dispensed In actual practice the best result will emerge It stands to reason, also, that there must be full opportunity for investigation of the condition which is being dealt with in each case if any of the methods of physical treatment are to be rationally applied, it must be possible to make an X ray examination, and if desirable to examine under an anæsthetic. Time must not be wasted in the physical treatment of cases of hopeless ankylosis or of small but painful adhesions which can be promptly cured by stretching under an anæsthetic All this seems to point to the justice of the conclusion that the combined physical treatment should be carried out in an institution specially devoted to it, and by a staff of the necessary experience

◆

Dentists and Military Service

THE position of dentists in Lord DERBY'S scheme does not seem to be entirely satisfactory Recently Mr TENNANT was asked whether he was aware that local tribunals were refusing to exempt or to postpone to a later call dentists duly qualified In his reply he stated that the cases were to be decided by local tribunals This condition of affairs is unsatisfactory, inasmuch as there will be no conformity of treatment, the exemptions varying with each tribunal, and that variation being determined largely by the constitution of the tribunal Surely some definite guiding rules should be issued, so that all could be dealt with on parallel, i e, equitable, lines It would have to be understood that the unregistered have no *locus standi*, and also the wants of districts must be carefully considered Injustice may arise if those attached as civilian dentists are exempted on account of such appointments Many of these appointments are purely local and have not been made after consideration of the position of other dentists in the same districts, and many of the individuals holding these appointments are of military age, and their work could quite easily be done by practitioners in the same district who are outside the scope of the group system Still further, consideration must be given to those holding school appointments The work done by these officials is of great national importance because they are making potential military efficients There is no doubt that a large number of dentists of military age can be called to the colours without disorganising the civilian wants, but it is essential that those individuals should be used to supply the dental needs of the army and should not be utilised as combatant officers

Mr F NEWLAND PEDLEY'S letter in our issue of Jan 29th is in this connexion worthy of the serious attention of the Army Medical Service The organisation of the dental services in our army is most indifferent and this is in a large measure due to the fact that it is in the hands of officials who can possess no special knowledge of dentistry The waste of public money over the treatment of the soldiers is well known, and has been mainly due to the fact that there has been no one in close touch with the authorities who possessed the necessary special knowledge Recently dental inspectors have been appointed, but in many instances these have been young men who have not held responsible positions in dental institutions these appointments are unsatisfactory in the sense that their holders may often be brought into contact with men more capable in their profession than they themselves can claim to be There is no doubt that the dental services of the army would be far better carried out if the Army Medical Service would delegate the work to a medically and dentally qualified officer with the rank and position commensurate with the importance of the position

There are proofs that unfamiliarity with the claims and achievements of modern dentistry prevails throughout the medical services. Medical officers of hospitals when dealing with cases of injury of the jaw too often omit to call in the aid of the dental surgeon, and many of our injured soldiers may have been doomed to permanent deformation of the jaw through this neglect The Eastern Command has, we understand, organised at Croydon a special hospital for dealing with cases of injuries of the jaw, and the result has proved to be most satisfactory If the Eastern Command can organise such a hospital why cannot the other commands do likewise? We think that there is an absolute necessity for grappling with the problem of fuller dental attention to the army, and public opinion is day by day becoming more and more alive to the necessity of the proper dental treatment of the troops The modern medical man realises that the properly trained dental surgeon's opinion is worthy of respect and that it is impossible without special knowledge to deal rationally with the problems which must arise in connexion with dentistry The services now command the activities of our leaders in every branch of medicine and pathology, we are certain that these officers would individually and collectively agree in the justice of the claim that the sailor and soldier should have the best dental aid

Annotations.

"Ne quid nimis"

INOCULATION OF CIVILIANS AGAINST THE ENTERIC GROUP

THE fact that so many soldiers are returning to this country convalescent or actually suffering from typhoid, paratyphoid A or paratyphoid B naturally gives rise to an apprehension that some danger to civilians might thus occur Hitherto there has been no evidence of this, but information has reached us that, at any rate in one district, there has been a rise in the notifications of the diseases coming under the enteric group, and in that district there are a number of soldiers recently returned from over seas Every precaution has been taken by the military authorities to guard against infection and prevent carriers from mixing with the general population No patient who has been diagnosed as suffering from one or more of these diseases is permitted to leave hospital until at least three negative bacteriological examinations have been made of the stools There may be some cases however, in which the disease has been so slight owing to previous inoculation that the man affected has not "reported sick and so the disease has escaped detection, nevertheless that man may possibly be a carrier It is probable that such cases are few It behoves the sanitary authorities also to take all necessary precautions and to ensure that all cases occurring among civilians should be at once isolated, but it is not easy to ensure that all patients are dealt with in an early stage, it is possible that some of the cases are of the ambulatory form and so may not be diagnosed. Such difficulties, however, are met with at all times, and the question arises whether the risks now run by civilians in places where military hospitals are situated are such that preventive inoculation should be strongly advocated Our attention has been drawn to an outbreak of typhoid and paratyphoid fever which has occurred in Reading, and our correspondent strongly urges preventive inoculation There is no doubt of the success that has followed the inoculation of the troops, but they are exposed to much greater danger than are civilians in this country, owing to the possible contamination of the water supply, and in warm countries, such as was the case in Gallipoli, by the food becoming infected by flies It is well known that ordinary precautions as regards cleanliness taken by those in charge of the sick will go a long way towards prevention of infection, and it is probably only in the event of the water or milk supply becoming contaminated that a serious outbreak is likely As far as the evidence goes at present we should not feel disposed to urge compulsory inoculation—such a proposal might be followed by an agitation which would be reflected among recruits, but that civilians should be *advised* to be inoculated against the enteric group is a proposition that might well be supported The information in regard to Reading is the first instance reported to us of an outbreak possibly attributable to returned soldiers More evidence would be required before any drastic steps could be taken by the sanitary authority with regard to the general population, but that inoculation might be a prudent step in those districts in which several cases have been notified amongst civilians cannot be denied

THE ADMINISTRATION OF THE PHARMACY ACTS

A SATISFACTORY statement in the annual report of the Pharmaceutical Society, which was presented to the Council of the Society at the February meeting, points to an increase in the number of names on the Register of chemists and druggists A contrary experience would not have been surprising, since such large numbers of pharmaceutical apprentices and students have joined the army But notwithstanding this fact nearly 1000 candidates entered for the qualifying examination last year, which is an increase of something like 15 per cent on the previous year It seems reasonable to assume that one of the causes of this increase was the desire on the part of students to obtain their qualification before joining the colours, and signs are *not* wanting that during the present and the next few years the number of candidates may be diminished to a material extent, for there is already a very heavy falling off in students A diminished Register may therefore be expected, but the reduction is not likely to be of such a serious nature as to cause public inconvenience, since the proportion of pharmacists to the population is now something like 1 to every 2000, a proportion which in some continental countries would be regarded as excessive In any case the standard of the qualifying examination will *not* be lowered in order to enlarge the Register The membership of the Society continues to grow, and now consists of almost exactly one half the number of those eligible for membership, which, for a voluntary Society, may be considered satisfactory Turning to the part of the report which deals with the administration of the penal clauses of the Pharmacy Acts, it is seen that the war has not interfered with the activity of the Society's law department, for over 1000 cases of alleged *infringement* were investigated and proceedings were instituted in no less than 300 cases, compared with 239 cases in the previous year In the majority of instances the defendants were unqualified drug store proprietors who had been usurping the functions of qualified pharmacists It is clearly the view of the Pharmaceutical Society that it is just as necessary in war time as in peace time that the public should be protected from the danger involved by the indiscriminate selling of poisons

THE TREATMENT OF PELLAGRA WITH SODIC CITRATE

WE had occasion in 1914[1] to call attention to the researches of Dr G Alessandrini and Dr A. Scala, showing that silica in a colloidal state produced in various animals an intoxication in which the clinical picture and pathological lesions corresponded completely to those of pellagra *These* observers, moreover, demonstrated that by causing monkeys to drink the opalescent water of pellagrous districts, which is also drunk by the inhabitants, a similar intoxication results, They came to the conclusion that the cause of this disease was the silica, and probably also the silicates, existing in the drinking water in a state of solution or colloidal suspension They added, however, that *not* all water which contained silica will cause this intoxication, since the silica is capable of forming, like the colloids, unstable combinations with the electrolytes, and these combinations may be innocuous They said, further, that carbonate of calcium and the alkaline carbonates prevent the toxicity of the silica Dr Alessandrini and Dr Scala now state *in a further* communication (*Il Policlinico, Practical* Section, Jan 16th, 1916) that it is not *sufficient to assert that* their conclusions do not *merit* consideration simply because the cause of pellagra is incontrovertibly connected with the *consumption* of maize, every part of which has been minutely analysed and experimented upon, without giving the clear, striking, and broad results obtained by them in their experiments Neither is it a valid objection which has been put forward by Sandwith that in Egypt, where pellagra is also *found, there* are no areas of silica, for the reason *that* the water of these localities has not been examined, and that it has never been denied *that argillous* strata exist in which the water lies which *afterwards* forms into springs and from which *they* may be contaminated Besides, it is incredible *to* them *that* a desert soil *like* that of Egypt should be wanting in silica In their former communication Dr Alessandrini and Dr Scala referred to ten cases of pellagra cured by intramuscular *injections* of sodic citrate, 1 c c of an aqueous solution of 10 per cent, leaving the patients in their original surroundings, at their ordinary occupation, and on their usual scanty diet. They have now collected a further number of cases, from various parts of Italy *treated* in the same manner In 44 out of 50 thus treated excellent results were obtained, especially when it is noted that there was no other factor to cast doubt on the curative effect of the remedy Of the remaining 6 cases, in 3 a marked improvement in the general condition was observed, although the cutaneous manifestations were but slightly improved Of the other 3, only 1 could be said to give an entirely negative result, and in this chronic articular rheumatism and endocarditis existed, while another was of advanced age and was subjected to a limited number only of injections The observers express the hope that extended trials will be given to this treatment, believing that, if the theory of the cause of pellagra is not recognised as proved, the benefit of the method will be more largely taken advantage of Then, where possible, the drinking water of pellagrous districts will be purified

---

[1] THE LANCET Sept 12th, 1914 p 713 April 7th, 1915 p 794

THE REGULATION OF PROSTITUTION IN SWEDEN

THE proposal in Sweden of a Royal Commission to abolish the regulation of prostitution by the police[1] has been investigated by the Swedish "Medicinalstyrelse," or Board of Health, and this department has solicited the opinions of various authorities throughout Sweden with the result that widely divergent views as to the efficacy of regulation appear to be held Although the proposals of the Commission, which are antagonistic to regulation, are endorsed by most of the authorities consulted, only a minority unequivocally urge the total abolition of regulation The authorities in favour of abolition have, in many cases, had considerable experience of regulation in the large towns which still countenance regulation, or, after having permitted it for some years, have abandoned it Stockholm, Gothenburg, Norrköping, Christianstad, and Sundsvall still retain regulation, while Malmö, Helsingborg, Uppsala, Lund, Jönköping, Eskilstuna, and Falun have abandoned it In Gothenburg, for example, the medical officer deputed to examine prostitutes, frankly states that he is unable to recommend the maintenance of regulation, whether it is made more stringent or more lenient The many objections to regulation are, he says, certainly not outweighed by the relatively slight sanitary advantages of this measure The sanitary authorities and the police of Malmö agree that the objections to regulation are so serious that abolition is practically inevitable Regulation, it appears, was introduced in Malmö towards the end of the "eighties" Early in 1905 the police ceased to register new prostitutes and early in 1908 the system was abolished, the vagrancy laws being applied in certain cases as a substitute These changes were followed by a marked reduction of prostitution in the streets, but it is not possible exactly to estimate the extent to which the application of the vagrancy laws to prostitutes was responsible for this reduction It is, however, certain that the vagrancy laws were far more effective and awe inspiring when applied as a substitute for regulation than when treated as a subsidiary to regulation It was found from a modified form of notification of venereal disease obtaining in Malmö that its incidence fluctuated much from year to year in the period 1892–1913, but that the abolition of regulation was followed by an appreciable fall in the incidence of this disease This fall may, it is admitted, have been due to other factors, but at any rate it shows that the abolition of regulation does not necessarily promote the spread of venereal disease, and that regulation as far as Malmö is concerned, is far from necessary

OCCUPATIONAL INJURIES DUE TO RADIUM

IN the *Journal of the American Medical Association* of Jan 1st Professor T Ordway, of Albany Medical College, has described the effects observed during a year's radium work at the Hunting Hospital Those who were applying radium in the treatment of patients noticed after a few weeks a slight though gradually increasing sensory disturbance in the finger tips, particularly on the ulnar side of the first phalanx of the thumb and the radial side of the terminal phalanges of the index and middle fingers of each hand. These symptoms began insidiously and consisted of blunting of sensibility of the finger tips, increased sensitiveness to heat and pressure, amounting at times to pa and anæsthesia of varying degrees They were o of proportion to the objective changes, which consisted of flattening of the natural ridges on the affected fingers with consequent changes in the finger prints, thickening of the horny layer of the epidermis with scaling, failure of the finger tips t resume their normal shape after pressure, a sort of pitting and upgrowth of the cuticle at the base of and underneath the nails, which became extreme brittle and tended to stand off from the finge The assistants and nurses were warned of the dangers and told not to handle the emanation tubes with the fingers but to use forceps But some handling is unavoidable For example, a medical practitioner began making routine applications of radium early in November, 1913 The increased in number until the latter part of January, 1914, after which they were few Afte some weeks the tips of the thumbs, particularly towards the ulnar side, and of the fore and middle fingers, especially towards the radial side, gradually became numb and deficient in sensibilit There was greatly increased sensitiveness to hea paræsthesia in the form of a peculiar feeling in th finger tips, and awkwardness in delicate manipula tions Small objects were frequently dropped an there was difficulty in taking pulses The affecte portion of the fingers became smooth and shiny an the ridges almost obliterated Later the epiderm became thickened, dry, and parchment like, and o pressure the finger tips remained indented fo some seconds The thickened horny layer becam wrinkled and cracked and desquamated The nail stood off from the flesh of the fingers and ther was a tendency to the upgrowth of tissue beneat the nail At present, although the patient ha handled radium for therapeutic application onl occasionally for almost a year, the dryness part anæsthesia and slight tenderness of the finger ti persist Changes in the blood of radium worker have been described by Gudzent and Halberstaedt —relative and absolute increase of lymphocytes a relative and absolute decrease in neutrophil These were also observed by Professor Ord Various general symptoms, such as headach malaise weakness unusual need of sleep irri bility, and disorders of menstruation have b described, but it is doubtful whether they are d to the radium or to other causes, such as cl confinement and tiring routine To preve these effects Professor Ordway advises that in t application of radium there should be a rotation of the staff, and affected persons should at least temporarily abandon the work Protection should be given as far as possible by screens in the form of boxes or plates about the radium The operating rooms should be well ventilated, particularly if any radium emanation is present

[1] THE LANCET Jan 8th 1916 p 89

JUVENILE CRIME

THERE is no need to dilate upon the many enactments for the welfare of our children recently placed on the Statute book. Some of these have now been in operation long enough to yield a good result, but the outbreak of war appears to have had a contrary effect A boy, aged 10, and his brother, aged 8, were charged at Leicester recently with setting fire to a council school The boys when arrested admitted that they wished to burn the school down Such a story points to a wave of lawlessness which can be noted among children, not in isolated parts of the country, but in all directions, and the connexion of this juvenile anarchy with the circumstances of the country in time of war may be presumed It can only be presumed as the figures for 1915 are not yet available, and those for 1914, which have just been issued, can only have been influenced to a minor degree by the war But these show that we have very inflammable material to deal with In juvenile courts 14,845 children were charged in 1914 with indictable offences This figure is 500 more than in 1913 Of non indictable offences, no fewer than 22,084 children were charged, making a total of 36,929, made up of 35,080 boys and 1849 girls Peace time or war time these figures are appalling enough It will be noted that they include a period of four months of war, and judging from the experiences in towns and country districts up and down the country the figures for 1915 will show a still greater increase in juvenile crime. Various reasons are combining to promote lawlessness among children The absence of fathers from home, the general unrest, the absorption of teachers in other things than pedagogy, and lastly, the picture palaces From a medico legal point of view, we are not sure that these places are sufficiently scrutinised Certain films appear designed to stir the love of danger among children in a most unfortunate way The children give immediate rein, oftentime in reckless and wanton bravado, to forms of emotion which find vent in crime Local authorities would do well to press for greater control over picture palaces, somewhat on the lines of what has been adopted in Liverpool, and, maybe, elsewhere—namely, day performances consisting of films of an educational or harmless character and approved of by the education authority, and the exclusion of children from evening performances, unless accompanied by parents or other adults Government intervention may otherwise be necessary

A LEECH IN THE NASAL CAVITY

IT is apparently a well recognised fact that, amongst the warmer countries skirting the Mediterranean Sea, leeches commonly gain access to the human body Usually they are ingested with drinking water, surface or well water being both potential harbourers of the leech When ingested it is of so small a size that it readily avoids detection, especially when water is drunk at night. It is said that the inhabitants avoid the possibility of swallowing the leech by drinking from the cupped hand Horses as well as men are attacked An instance of a soldier harbouring a leech is reported by Dr S F Harmer in the *Journal of the Royal Naval Medical Service* for January The patient was recovering from a shell wound when he began to suffer from headaches, frequent nose bleeding, and gastric pains At one time typhoid was suspected In this state he remained for some time until he came to England, passing through a phase of double tertian malaria in the meantime Three days after his return the leech was seen by the nurse in the nostril and removed The patient rapidly recovered. The length of the animal was three and a half inches The favourite habitat is the posterior nares behind the soft palate, but they may gain the region of the larynx The bleeding they induce may even be fatal It is probable that more instances of this character may be forthcoming, and any persistent bleeding from the upper respiratory passages should stimulate a search for this animal

THE SALE OF LAUDANUM

THE Council of the Pharmaceutical Society, at their February meeting, passed a resolution in the form required by statute, declaring that preparations of opium containing 0 75 per cent of morphine ought to be added to Part I of the Poison Schedule. The resolution was in the following terms —

> That by virtue and in exercise of the powers vested in the Council of the Pharmaceutical Society of Great Britain by the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act 1908, the said Council does hereby resolve and declare that the article in Part I of the Schedule to the last-named Act, "opium and all preparations or admixtures containing 1 or more per cent of morphine" ought to be removed therefrom, and that the article, 'opium and all preparations or admixtures containing 0 75 per cent of morphine" ought to be added thereto

This resolution will bring the "laudanum" of the British Pharmacopœia, 1898, into the first *part of* the Poison Schedule In view of the known attitude of the Privy Council in relation to this matter, there can be no doubt that the Pharmaceutical Society's recommendation will be approved and gazetted in due course The steps that have led up to this action have already been recorded in THE LANCET, and it is satisfactory to know that the Pharmaceutical Society has taken what is undoubtedly the proper course

DEATHS OF AMERICAN MEDICAL MEN IN 1915

THE New Year number of the *Journal of the American Medical Association* gives its usual annual summary of the deaths of medical men in the United States and Canada. Based on a conservative estimate of 156,000 practitioners, the annual death-rate was 15·71 per 1000, being exactly the average for the last 14 years The chief causes of death in the order named were the same as for the previous year—viz., senility (400), heart disease (218), cerebral hæmorrhage (218), pneumonia (154), accident (104), and nephritis (90) The average age at death was a little over 59, 212 deaths occurred between 81 and 90, 30 between 91 and 100, while one physician attained the age of 102 years The average number of years of practice was 32½ The causes assigned for the deaths from accident were automobile, 23, falls and drowning, each 16 (of the latter, 5 were drowned in attempting to save lives), poison, 11, automobile and railway accidents, each 10, burns, 4, firearms and by injuries from animals, manner In 44 out of 50 thus treated excellent results were obtained, especially when it is noted that there was no other factor to cast doubt on the curative effect of the remedy Of the remaining 6 cases, in 3 a marked improvement in the general condition was observed, although the cutaneous manifestations were but slightly improved Of the other 3, only 1 could be said to give an entirely negative result, and in this chronic articular rheumatism and endocarditis existed, while another was of advanced age and was subjected to a limited number only of injections The observers express the hope that extended trials will be given to this treatment, believing that, if the theory of the cause of pellagra is not recognised as proved, the benefit of the method will be more largely taken advantage of Then, where possible, the drinking water of pellagrous districts will be purified

THE REGULATION OF PROSTITUTION IN SWEDEN

THE proposal in Sweden of a Royal Commission to abolish the regulation of prostitution by the police[1] has been investigated by the Swedish "Medicinalstyrelse," or Board of Health, and this department has solicited the opinions of various authorities throughout Sweden with the result that widely divergent views as to the efficacy of regulation appear to be held Although the proposals of the Commission, which are antagonistic to regulation, are endorsed by most of the authorities consulted, only a minority unequivocally urge the total abolition of regulation The authorities in favour of abolition have, in many cases, had considerable experience of regulation in the large towns which still countenance regulation, or, after having permitted it for some years, have abandoned it Stockholm, Gothenburg, Norrköping, Christianstad, and Sundsvall still retain regulation, while Malmö, Helsingborg, Uppsala, Lund, Jönköping, Eskilstuna, and Falun have abandoned it In Gothenburg, for example, the medical officer deputed to examine prostitutes, frankly states that he is unable to recommend the maintenance of regulation, whether it is made more stringent or more lenient The many objections to regulation are, he says, certainly not outweighed by the relatively slight sanitary advantages of this measure The sanitary authorities and the police of Malmö agree that the objections to regulation are so serious that abolition is practically inevitable Regulation, it appears, was introduced in Malmö towards the end of the "eighties" Early in 1905 the police ceased to register new prostitutes and early in 1908 the system was abolished, the vagrancy laws being applied in certain cases as a substitute These changes were followed by a marked reduction of prostitution in the streets, but it is not possible exactly to estimate the extent to which the application of the vagrancy laws to prostitutes was responsible for this reduction It is, however, certain that the vagrancy laws were far more effective and awe inspiring when applied as a substitute for regulation than when treated as subsidiary to regulation. It was found from a modified form of notification of venereal disease obtaining in Malmö that its incidence fluctuated much from year to year in the period 1892–1913, but that the abolition of regulation was followed by an appreciable fall in the incidence of this disease This fall may, it is admitted, have been due t other factors, but at any rate it shows that th abolition of regulation does not necessarily prom the spread of venereal disease, and that regulat as far as Malmö is concerned, is far from nece

OCCUPATIONAL INJURIES DUE TO RADIUM

IN the *Journal of the American Medical Asso tion* of Jan 1st Professor T Ordway, of Alb Medical College, has described the effects obs during a year's radium work at the Hunting Hospital Those who were applying radium in th treatment of patients noticed after a few wee a slight though gradually increasing sensory d turbance in the finger tips, particularly on the uln side of the first phalanx of the thumb and th radial side of the terminal phalanges of the in and middle fingers of each hand These sympto began insidiously and consisted of blunting o sensibility of the finger tips, increased sensitiven to heat and pressure, amounting at times to pa and anæsthesia of varying degrees They were o of proportion to the objective changes, which co sisted of flattening of the natural ridges on th affected fingers with consequent changes in th finger prints, thickening of the horny layer of th epidermis with scaling, failure of the finger tips t resume their normal shape after pressure, a sort o pitting and upgrowth of the cuticle at the base o and underneath the nails, which became extrem brittle and tended to stand off from the finger The assistants and nurses were warned of th dangers and told not to handle the emanatio tubes with the fingers but to use forceps Bu some handling is unavoidable For example, a medical practitioner began making routine appli cations of radium early in November, 1913 The increased in number until the latter part o January, 1914, after which they were few Afte some weeks the tips of the thumbs, particular towards the ulnar side, and of the fore and middle fingers, especially towards the radial side, grad ally became numb and deficient in sensibilit There was greatly increased sensitiveness to hea paræsthesia in the form of a peculiar feeling in the finger tips, and awkwardness in delicate manipula tions Small objects were frequently dropped an there was difficulty in taking pulses The affected portion of the fingers became smooth and shiny an the ridges almost obliterated Later the epidermis became thickened, dry, and parchment like, and o pressure the finger tips remained indented fo some seconds The thickened horny layer became wrinkled and cracked and desquamated The nails stood off from the flesh of the fingers and there was a tendency to the upgrowth of tissue beneath the nail At present, although the patient has handled radium for therapeutic application only occasionally for almost a year, the dryness part anæsthesia and slight tenderness of the finger tip persist Changes in the blood of radium workers have been described by Gudzent and Halberstaedt —relative and absolute increase of lymphocytes an relative and absolute decrease in neutrophile These were also observed by Professor Ord Various general symptoms, such as headach malaise weakness unusual need of sleep irrita bility, and disorders of menstruation, have b described, but it is doubtful whether they are d to the radium or to other causes, such as clo confinement and tiring routine To preve these effects Professor Ordway advises that in th application of radium there should be a rotation of the staff, and affected persons should at least temporarily abandon the work. Protection should be given as far as possible by screens in the form of boxes or plates about the radium. The operating rooms should be well ventilated, particularly if any radium emanation is present.

JUVENILE CRIME.

THERE is no need to dilate upon the many enactments for the welfare of our children recently placed on the Statute book. Some of these have now been in operation long enough to yield a good result, but the outbreak of war appears to have had a contrary effect. A boy, aged 10, and his brother, aged 8, were charged at Leicester recently with setting fire to a council school. The boys when arrested admitted that they wished to burn the school down. Such a story points to a wave of lawlessness which can be noted among children, not in isolated parts of the country, but in all directions, and the connexion of this juvenile anarchy with the circumstances of the country in time of war may be presumed. It can only be presumed as the figures for 1915 are not yet available, and those for 1914, which have just been issued, can only have been influenced to a minor degree by the war. But these show that we have very inflammable material to deal with. In juvenile courts 14,845 children were charged in 1914 with indictable offences. This figure is 500 more than in 1913. Of non-indictable offences, no fewer than 22,084 children were charged, making a total of 36,929, made up of 35,080 boys and 1849 girls. Peace-time or war-time these figures are appalling enough. It will be noted that they include a period of four months of war, and judging from the experiences in towns and country districts up and down the country the figures for 1915 will show a still greater increase in juvenile crime. Various reasons are combining to promote lawlessness among children. The absence of fathers from home, the general unrest, the absorption of teachers in other things than pedagogy, and lastly, the picture palaces. From a medico-legal point of view, we are not sure that these places are sufficiently scrutinised. Certain films appear designed to stir the love of danger among children in a most unfortunate way. The children give immediate rein, oftentime in reckless and wanton bravado, to forms of emotion which find vent in crime. Local authorities would do well to press for greater control over picture palaces, somewhat on the lines of what has been adopted in Liverpool, and, maybe, elsewhere—namely, day performances consisting of films of an educational or harmless character and approved of by the education authority, and the exclusion of children from evening performances, unless accompanied by parents or other adults. Government intervention may otherwise be necessary.

A LEECH IN THE NASAL CAVITY.

IT is apparently a well-recognised fact that, amongst the warmer countries skirting the Mediterranean Sea, leeches commonly gain access to the human body. Usually they are ingested with drinking water, surface or well water being both potential harbourers of the leech. When ingested it is of so small a size that it readily avoids detection, especially when water is drunk at night. It is said that the inhabitants avoid the possibility of swallowing the leech by drinking from the cupped hand. Horses as well as men are attacked. An instance of a soldier harbouring a leech is reported by Dr. S. F. Harmer in the *Journal of the Royal Naval Medical Service* for January. The patient was recovering from a shell wound when he began to suffer from headaches, frequent nose-bleeding, and gastric pains. At one time typhoid was suspected. In this state he remained for some time until he came to England, passing through a phase of double tertian malaria in the meantime. Three days after his return the leech was seen by the nurse in the nostril and removed. The patient rapidly recovered. The length of the animal was three and a half inches. The favourite habitat is the posterior nares behind the soft palate, but they may gain the region of the larynx. The bleeding they induce may even be fatal. It is probable that more instances of this character may be forthcoming, and any persistent bleeding from the upper respiratory passages should stimulate a search for this animal.

THE SALE OF LAUDANUM.

THE Council of the Pharmaceutical Society, at their February meeting, passed a resolution in the form required by statute, declaring that preparations of opium containing 0·75 per cent. of morphine ought to be added to Part I. of the Poison Schedule. The resolution was in the following terms:—

> That by virtue and in exercise of the powers vested in the Council of the Pharmaceutical Society of Great Britain by the Pharmacy Act 1868, as amended by the Poisons and Pharmacy Act, 1908, the said Council does hereby resolve and declare that the article in Part I. of the Schedule to the last-named Act, "opium and all preparations or admixtures containing 1 or more per cent. of morphine" ought to be removed therefrom, and that the article, "opium and all preparations or admixtures containing 0·75 per cent. of morphine" ought to be added thereto.

This resolution will bring the "laudanum" of the British Pharmacopœia, 1898, into the first part of the Poison Schedule. In view of the known attitude of the Privy Council in relation to this matter, there can be no doubt that the Pharmaceutical Society's recommendation will be approved and gazetted in due course. The steps that have led up to this action have already been recorded in THE LANCET, and it is satisfactory to know that the Pharmaceutical Society has taken what is undoubtedly the proper course.

DEATHS OF AMERICAN MEDICAL MEN IN 1915.

THE New Year number of the *Journal of the American Medical Association* gives its usual annual summary of the deaths of medical men in the United States and Canada. Based on a conservative estimate of 156,000 practitioners, the annual death-rate was 15·71 per 1000, being exactly the average for the last 14 years. The chief causes of death in the order named were the same as for the previous year—viz., senility (400), heart disease (218), cerebral hæmorrhage (218), pneumonia (154), accident (104), and nephritis (90). The average age at death was a little over 59, 212 deaths occurred between 81 and 90, 30 between 91 and 100, while one physician attained the age of 102 years. The average number of years of practice was 32½. The causes assigned for the deaths from accident were: automobile, 23, falls and drowning, each 16 (of the latter, 5 were drowned in attempting to save lives), poison, 11, automobile and railway accidents, each 10, burns, 4, firearms and by injuries from animals, each 2, and asphyxiation, sunstroke, privation, lightning, and explosion, 1 each The 44 doctors who ended their lives by suicide selected the following methods Firearms, 17, poison, 15 cutting instruments, 5, cause not stated, 3, strangulation, 2, and asphyxiation and jumping from a high place, each 1 Of the 21 homicides, 18 were due to firearms, 1 to hanging, and 2 to other means, and of these deaths 7 occurred in feuds or affrays Two medical men died in prison, and 9 lost their lives either in battle on land or by the sinking of ships on which they were medical officers Concerning the civil positions of those who died, 1 had been a member of Congress, 2 governors of states, 4 United States consuls, 11 members of State senates, 39 members of the lower houses of legislatures, 35 had been mayors, 33 aldermen, 52 had served as justices of the peace, as clerks in the government service, or in various other civil positions, 15 had been postmasters, 24 editors of medical or lay journals, 19 had been clergymen, of whom 4 were foreign missionaries, 4 had been attorneys, 107 druggists, 40 bankers, 16 medical directors of life insurance companies, 10 dentists, 3 presidents of railway companies, 6 surgeons on steamships, and 4 chemists The labour of compiling such a summary must be very considerable, and we are indebted to the American Medical Association for the interesting light which it throws on the career of the medical practitioner on the other side of the Atlantic Violent death, whether self inflicted or from without, is startlingly frequent, and in the opposite sense, death from old age shows a higher figure than might have been expected The variety of civil position is also worthy of note No such figures are available in this country, and an overworked Registrar General's staff could hardly be asked to supply them at the present time But we should expect to find that the medical man in this country leads, on the average, a more strictly professional life than his colleagues across the water, dies much less often from violence, but more rarely reaches the quiet cessation of his activities in an extreme old age

---

IT is the intention of the Queen to unveil the memorial to Florence Nightingale in the crypt of St Paul's Cathedral on Monday next, Feb 14th The memorial has been erected by the sculptor, Mr Arthur G Walker

---

Professor Arthur Keith is giving a course of lectures on *the Anatomy of the Human Body* for first aid and ambulance students in the theatre of the Royal College of Surgeons, Lincoln's Inn fields, at 5 30 P M, on Mondays, Wednesdays, and Fridays, from Feb 14th to May 5th. Illustrative anatomical specimens will be on exhibition in the theatre from 4–7 P M on each lecture day, and from 10 A.M to 5 P M on the succeeding day in the hall of the museum

---

AT the Section of Odontology of the Royal Society of Medicine a debate will be held on Monday Feb 28th, at 5 30 P M, to discuss War Injuries of the Jaws An exhibition of dental splints and other apparatus illustrating the subject will be open from Tuesday, Feb 22nd, to Monday, Feb 28th, between 11 and 6 30 Anyone wishing to exhibit is asked to communicate with the honorary secretary by the 14th instant Members of the Section of Surgery are specially invited to the debate

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

The Midwives (Scotland) Act, 1915 The Central Midwives Board for Scotland

THE Central Midwives Board for Scotland has been provisionally constituted as follows the appointing body being added to the names in brackets Sir Archibald Buchan Hepburn (Association of County Councils for Scotland), Sir Robert Kirk Inches (Convention of the Royal Burghs of Scotland), The Lady Susan Gordon Gilmour (Queen Victoria Jubilee Institute for Nurses Scottish Branch), Dr Archibald Campbell Munro (Society of Medical Officers of Health of Scotland), Professor Sir John Halliday Croom (University Courts of the Universities of Edinburgh and St Andrews, conjointly), Professor Murdoch Cameron (University Courts of the Universities of Glasgow and Aberdeen, conjointly), Dr James Haig Ferguson (Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow, conjointly) and Dr Michael Dewar and Dr John Wishart Kerr (Scottish Committee of British Medical Association) The Lord President of the Council can nominate three members of the Board, but as yet has appointed only Lady Balfour of Burleigh

The Local Government Board of Scotland has issued a circular to the local authorities calling their attention to those provisions of the Midwives (Scotland) Act which directly affect them The circular gives a summary of the local authority's duties of superintendence and supervision under sections 16 and 17, and points out that it may delegate its powers and duties to a committee, it also calls attention to the obligation likely to be laid upon such authorities to contribute to the general expenses of the Central Midwives Board when the fees payable by candidates for registration prove insufficient for the purpose One of the provisions of immediate interest to which attention is directed is that by which local supervising authorities are authorised to contribute towards the training of midwives within or without their respective areas in such manner and to such extent as may be approved by the Local Government Board

Edinburgh University Court

At a recent court of Edinburgh University, on the recommendation of the Senatus, it was resolved that students who had attested and had been accepted for military service, and who had completed five terms of study of anatomy, should be permitted to appear for the professional examination in anatomy in March next It was resolved also that, for the present year, students who commenced medical study in winter, and who are now in their third year, should be allowed to appear for examination in March next, instead of in the following July It was intimated that the sum of £237 has been received from the Scottish Association for the Medical Education of Women for the purpose of founding a prize for women medical students The precise conditions of award will be announced later The following additional examiners were appointed Dr George Pr Yule, Medical Officer of Health, Fifeshire (Public Health Laboratory Work) Professor H R Dea Victoria University of Manchester (Pathology) Dr W G Aitchison Robertson (Forensic Medicine) Dr Charles Porter Medical Officer of Health

Marylebone (Public Health, &c), and Dr George F Barbour Simpson (Midwifery)

Edinburgh Insurance Committee

At a meeting of the Administration Subcommittee of the Edinburgh Insurance Committee the clerk submitted a statement of payments to doctors and chemists during the year 1915 The payments to doctors amounted to £25,448 10s 8d, as against £30,802 3s 2d during 1914 The payments for the year 1915 were by way of an advance at the rate of 1s 4d per person on each doctor s list, pending an adjustment of the lists as regards persons who have joined H.M Forces and are no longer entitled to medical benefit The payments to chemists for supply of drugs medicines &c, during 1915 amounted to £5823 14s 5½d, as against £6898 2s 6d for 1914 The amounts paid for October, November, and December, 1915, represent 90 per cent of amounts claimed, 10 per cent having been retained pending a complete check of the prescription forms for these months The list of doctors under agreement with the Edinburgh Insurance Committee as revised in January numbers 119 There are 108 chemists and dealers in appliances and half a dozen dealers in prescribed appliances only

The Royal Public Dispensary, Edinburgh

The annual meeting in connexion with the Royal Public Dispensary of Edinburgh was held in the City Chambers on Jan 29th, Lord Provost Sir Robert Inches presiding Mr R C Gray, S S C, the honorary secretary, submitted the annual report of the managers, which stated that the past year was the 139th of the history of the dispensary, and that even in the special and trying conditions the institution continued to do much good work among the suffering poor and to maintain its place among the charities of the city The dispensary provided advice, medicines, and surgical appliances and assistance all free of charge, and the number who had been relieved during the past year is 3241, those who had been attended at their own homes 1420 The operation of the Insurance Act, as was to be expected, had affected the number of adult working men who applied to the institution but another cause of the diminution of the numbers was the impossibility of maintaining the normal attendance of the medical staff at the present time Six out of the eight ordinary physicians are absent on active service The managers felt that special acknowledgment was due to Dr J G Cattanach and Dr G D Mathewson and also to Dr A B Darling who, with the assistance of medical students, had done their utmost to give attention and care to the patients

Medical Service for Highlands and Islands

In a large number of northern parishes medical practitioners have concluded agreements with the Highlands and Islands Medical Service Board, under which they will give medical attendance to the families and dependants of insured persons, uninsured persons of the crofter and cottar class with their families and dependants and others in similar circumstances who would find an ordinary fee for medical attendance too heavy for them The arrangement is that the doctors shall charge these persons a sum not exceeding 5s for first visit and 2s 6d for each succeeding visit in the same illness, the distance of the patient s house from the doctor s making no difference to the fee An additional moderate fee is chargeable when the practitioner supplies the medicine The midwifery fee including fees for subsequent visits if necessary, has been fixed at £1. The board has issued for use in the various districts under its jurisdiction notices which can be used as posters explanatory of its objects and scope Under the explanatory paragraphs, which are, of course, of general application, is printed a schedule giving the names of the medical men whose services are to be had in the particular district for which the notice is intended, together with the area within which they have agreed to give attendance

Feb 7th

IRELAND

(FROM OUR OWN CORRESPONDENTS)

The Gratitude of a Board of Guardians

SOME weeks ago the Enniscorthy guardians granted to Mr T J Kelly, one of their medical officers, on his retirement a superannuation allowance of £100 a year He had spent 38 years in their service Mr Kelly wrote to the Local Government Board, pointing out that he had not been granted the full allowance to which he considered himself entitled. The guardians, taking umbrage at his action, thereupon rescinded their previous resolution and fixed his retiring allowance at £50 per annum The decision was declaredly made, in the words of the guardian who moved the resolution, "to punish the doctor for writing to the Local Government Board" The incident is illustrative of the unfortunate position of the Poor-law medical officer as regards retiring allowance in that he is entirely dependent on the will of the guardians

A Medical Mayor

Mr J J O Sullivan, L.R C S Irel. has been elected Mayor of Waterford He has been for some time an alderman of that city, and has filled the office of High Sheriff. Mr O Sullivan is an active member of the Irish Medical Committee, and an examiner at the Apothecaries Hall

The Forster Green Hospital, Belfast

At the annual meeting of the friends of this hospital, held on Jan. 25th, it was reported that 237 patients were treated during the year 1915, as against 323 in 1914 On the other hand, the average period of treatment was 20 5 weeks as against 13 49 weeks in 1914 It is interesting to note that while the subscriptions were a few pounds down, the total amount in the household expenses (despite the increase of prices) was increased by only £120 upon an expenditure of £2500 It is proposed to pay off £672 of the building debt instead of £1000 One of the clerical speakers criticised the city corporation of Belfast for a very serious omission in their tuberculosis scheme in failing to provide for the inspection of schools, which, he said, in Belfast were 'hot beds of disease, and they would never get this scourge (consumption) under control until they adopted a system of school medical inspection. School medical inspection is, however, likely to be inadequately performed during the war

The Belfast Hospital for Sick Children

At the annual meeting of the supporters of this charity held on Jan. 27th, the report presented by the medical staff showed that 631 intern and 4034 extern cases were treated during 1915 The clinics are being largely attended by senior medical students The financial statement indicated that

es was investigated 12 of d a dysentery Widal, while

research are often difficult to estimate the significance of tely, neither Dr Ledingham on on the subject Are we to ffered by those attacked were yphosus or the B dysenteriæ mbined? The symptoms and y Dr Rees, do not suggest that ier typhoid fever or dysentery ion, more probable that the estion of the ordinary sewage be correct, the epidemic is a far to prove the fact, which is ge-polluted water may give rise the specific organism of enteric

M REPORTS

Wakefield (Annual Report for the number of cases under treatment the average daily number resident e 338 direct admissions and 26 of patients discharged was 171, 7 36 per cent based on the direct 183 deaths, making a death rate of rage daily number resident. General ipal cause of death in 44 cases and J S Bolton, the medical super ter an experience of several years he t life is much more healthy and ified and partial out-door treatment the employment of permanent verandahs that the general use of inexpensive out-orms which enables meals to be provided the whole of the patients in the institution, tly improves the health and adds to the comfort es and staff, but also simplifies the administra dds to the general hygiene of the wards sylum the wards are little used during the part of the year except for sleeping purposes egard to the research work carried out in the gical laboratory Dr Bolton has recently completed a The Brain in Health and Disease," and has also in tion with Dr W Robinson, finished the systematic ation of the brain in a case of long standing per blindness in which central vision had been largely ed Dr H Devine during the year published papers o subjects—namely, the Clinical Significance of nic Symptoms and the Biological Significance of ns Dr Robinson published a paper on Some ul Cases of So-called General Paralysis of the and Mr H S Gettings and Dr Ethel Waldron published paper on the Detection of a Dysentery Carrier — Canley Hall 6 new cases of imbecile boys were ed during the year One of these, together with ases, was sent to the chronic block Of the 5 other ssions 2 attended school 2 were unfit and 1 was oung The number of boys on the school register was ith an average daily attendance of 26 The girls unately, continued to be scattered throughout the wards

ford County and City Lunatic Asylum (Annual Report Year ending March 31st 1915) —The total number of under treatment during the year was 603 the average number resident being 520 The total number of nts admitted for the year 1914 was 85, of whom 12 transferred from other asylums The prevalent forms ental disorder in the direct admissions were Mania 20, ncholia 8, dementia 11, delusional insanity 8, ptic insanity, 1, confusional states 5, imbecility, 14, r 4, general paralysis of the insane 2 Of the chief ative factors alcoholism was assigned in 9 cases syphilis nd neurotic and neuropathic heredity in 35 It is note thy in what a large percentage of cases in which accurate rmation had been obtained insane heredity and con ital mental defect were found to be the dominating factor termining the issue There has always been in residence a larger ratio of related patients in this asylum than in most county asylums The discharges numbered 26, with a recovery rate, calculated on the direct admissions, of 17 8 per cent There were 38 deaths, making a mortality of 7 3 per cent, based on the daily average number resident Senile decay was the cause of death in 13 cases, tuberculosis in 5, general paralysis of the insane in 1, and chronic Bright's disease in 7 A post-mortem examination was performed in 76 3 per cent of the cases

Govan District Asylum, Cardonald, Glasgow (Annual Report for the Year ending May 14th, 1915) —The total number of cases under treatment during the year was 935, the daily average number resident being 665 6 There were admitted in all 280 patients, and there were discharged 132, of whom 80 were recovered The percentage of recoveries to the total admissions was 28 5 One male patient was discharged recovered after having been under treatment for 19 years The deaths were at the rate of 16 3 per cent of the average daily number resident, and numbered 109 Of these 60 were due to diseases of the nervous system (including 26 due to general paralysis of the insane), 6 to heart disease, 8 to lung disease, 5 to abdominal disease, 6 to old age, and 22 to various general diseases Of the patients admitted 70 7 per cent. were in a weak state of health, and many were suffering from the terminal stage of bodily diseases Alcoholic excess was an important causative factor in 21 per cent of the men and 5 9 per cent. of the women General paralysis was present in 17 9 per cent of the men and 4 2 per cent of the women With regard to the influence of the war on the number of admissions the number admitted for the period of the war under review was less than for corresponding periods of previous years, and in no single case could it be said that the war played the principal rôle in the causation of the mental disorder

The Coppice Mental Hospital for the County and City of Nottingham (Annual Report for the Year 1914) —The total number of cases under treatment during the year was 128 of whom 7 were voluntary boarders The average daily number resident was 93 The admissions amounted to 28, which was the largest number for any year since 1899 Many applications for admission to the female side had to be refused, as there were no vacancies In addition to the 28 admissions 2 men and 5 women were admitted as voluntary boarders without certificates The chief forms of mental disorder in the admissions were as follows 7 suffered from forms of mania or mental exaltation, 4 from melancholia, 6 from confusional states, 6 from primary dementia, and 3 from general paralysis of the insane The prospects of recovery were regarded as fair in 14 of the admissions 25 per cent. of the cases admitted were ascertained to have a definite family history of insanity or other allied neurosis 20 patients were discharged, yielding the good percentage of 50 on the direct admissions The duration of the attack in the recovered cases varied from 2 to 14 months, and in 10 of the 11 the duration was less than 12 months There were 8 deaths, making a death rate of 8 59 per cent. of the average number resident The new shelter for open-air treatment proved very useful in acute cases, and gave most beneficial results in the subduing of excitement and the inducing of sleep and appetite

Waterford District Lunatic Asylum (Annual Report for the Year 1914) —The total number of cases under treatment during the year was 709 the daily average number resident being 642. The admissions numbered 67, and were 2 more than in 1913 which was the lowest number for 30 years The varieties of mental disease were as follows Mania, 30 cases, melancholia, 11, delusional insanity 10, congenital mental deficiency, 4, insanity with epilepsy, 1, insanity with gross brain lesion, 1, dementia, 6 Four persons were not insane on admission The principal causes of mental breakdown were in the following order of frequency Hereditary predisposition, 29 cases, mental stress or worry 18, alcoholic cases 11, mental deficiency 6 The discharges numbered 36—25 males and 11 females. Of these, 18 males and 6 females were recovered The recovery rate, calculated on the total number admitted, was 35 8 per cent, being 3 5 per cent more than the previous year There were 31 deaths 9 more than in 1913 The mortality rate calculated on the daily average number resident was 4 8 per cent This was 1 3 per cent more than in 1913 but was still much below the average death rate in the other Irish asylums—viz., 7 2 per cent

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 7301 births and 5098 deaths were registered during the week ended Saturday, Feb 5th The annual rate of mortality in these towns which had been 13 9, 14 2, and 14 0 per 1000 in the three preceding weeks, rose in the week under notice to 14 7 per 1000 of their aggregate population, estimated at 18,136,180 persons at the middle of the year 1914 During the first five weeks of the current quarter the mean annual death rate in these towns averaged 14 2, against a corresponding rate of 13 6 in London The annual death rate last week ranged from 3 4 in Ilford, 4 9 in Swindon 8 2 in Hornsey, in East Ham, and in Newport (Mon), 8 6 in Northampton, and 9 1 in Bournemouth, to 20 6 in Liverpool, 20 8 in Burnley, 21 1 in South Shields, 22 2 in Dewsbury, and 24 3 in West Hartlepool

The 5098 deaths from all causes were 238 in excess of the number in the previous week, and included 340 which were referred to the principal epidemic diseases, against 305 and 314 in the two preceding weeks Of these 340 deaths, 104 resulted from whooping-cough, 70 from infantile diarrhœal diseases, 63 from diphtheria 62 from measles, 28 from scarlet fever 12 from enteric fever, and 1 from small pox The death rate from these diseases was equal to 1·0, against 0 9 per 1000 in each of the two preceding weeks The deaths attributed to whooping cough which had been 78, 74, and 80 in the three preceding weeks, further rose to 104, and included 28 in London, 10 in Liverpool, 9 in Birmingham, 5 each in Leicester and Manchester, and 4 each in West Ham, Coventry and Leeds The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 60, 60, and 68 in the three preceding weeks, further rose to 70, of which 17 were recorded in London, 4 each in Birmingham and Sheffield and 3 each in Stoke-on Trent, Leeds, and Liverpool The fatal cases of diphtheria, which had been 84, 79 and 70 in the three preceding weeks, further fell to 63, 16 deaths were registered in London 4 each in Portsmouth, Plymouth, and Liverpool, and 3 each in Bristol, Stoke-on Trent, Birmingham, and St Helens The deaths attributed to measles, which had declined from 81 to 62 in the four preceding weeks, were again 62 last week, and included 8 in London, 6 each in Nottingham, Stockport, and Burnley, and 5 each in Bristol, Leicester and Leeds The deaths referred to scarlet fever, which had been 23 10, and 25 in the three preceding weeks, rose to 28, of which 7 occurred in London, 4 in Stoke-on Trent, and 2 each in Manchester, Sheffield and Newcastle-on Tyne The fatal cases of enteric fever which had been 9 in each of the three preceding weeks, rose to 12, and included 3 in Wigan and 2 in Reading The death from small pox was registered in Salford

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2224, 2257, and 2189 at the end of the three preceding weeks, further fell to 2153 on Saturday last, 253 new cases were admitted during the week, against 244 286 and 260 in the three preceding weeks These hospitals also contained on Saturday last 1557 cases of diphtheria 143 of whooping-cough, 48 of enteric fever and 47 of measles, but not one from small pox The 1206 deaths from all causes in London were 4 in excess of the number in the previous week, and corresponded to an annual death rate of 13 9 per 1000 The deaths referred to diseases of the respiratory system, which had been 264, 254, and 231 in the three preceding weeks, fell to 225 in the week under notice and were 272 below the number registered in the corresponding week of last year

Of the 5098 deaths from all causes in the 96 towns, 191 resulted from violence and 377 were the subject of coroners' inquests while 1415 occurred in public institutions The causes of 58 or 1 1 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in Leeds, Bristol West Ham Bradford, Hull, Newcastle-on Tyne, and in 67 other smaller towns Of the 58 uncertified causes, 13 were registered in Liverpool, 10 in Birmingham 3 each in Gateshead and London, and 2 each in 10 other towns

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2 355 300 persons at the middle of this year, 1034 births and 606 deaths were registered during the week ended Saturday, Feb 5th The annual rate of mortality in these towns which had been 15 4 14 4 and 14 6 per 1000 in the three preceding weeks fell to 13 4 per 1000 in the week under notice During the first five weeks of the current quarter the mean annual death rate in these towns averaged 14 7, against a corresponding rate of 14 2 per 1000 in the large English towns Among the several towns the death rate last week ranged from 2 3 in Clydebank, 9 9 in Motherwell, and 11 4 in Edinburgh, to 19·4 in Paisley, 20 1 in Greenock, and 21 5 in Perth

The 606 deaths from all causes were 52 fewer than the number in the previous week, and included 50 which were referred to the principal epidemic diseases, against 43 and 59 in the two preceding weeks Of these 50 deaths, 22 resulted from measles, 14 from diphtheria, 7 from scarlet fever, 6 from infantile diarrhœal diseases, and 1 from enteric fever, but not one from whooping-cough or from small pox The annual death rate from these diseases was equal to 1 1, against a corresponding rate of 1 0 per 1000 in the large English towns The deaths attributed to measles which had been 23, 19, and 29 in the three preceding weeks, fell to 22, and included 6 in Greenock, 5 in Glasgow, 4 in Coatbridge, and 2 each in Edinburgh and Ayr The deaths referred to diphtheria which had been 13, 8, and 15 in the three preceding weeks, were 14 last week, of which 5 occurred in Glasgow and 4 in Edinburgh The fatal cases of scarlet fever, which had declined from 18 to 7 in the four preceding weeks, were again 7 last week and included 5 in Glasgow The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 13, 4, and 13 in the three preceding weeks, fell to 6, of which 2 occurred in Glasgow The fatal case of enteric fever was recorded in Dundee

The deaths referred to diseases of the respiratory system, which had been 114, 92, and 97 in the three preceding weeks, fell to 73 in the week under notice, and were 229 below the number registered in the corresponding week of last year The deaths from violence numbered 23, against 37 and 23 in the two preceding weeks

HEALTH OF IRISH TOWNS

In the 19 town districts of Ireland, with populations exceeding 10,000 persons at the last Census, 530 births and 388 deaths were registered during the week ended Saturday, Jan 29th The annual rate of mortality in these towns, which had been 21 0, 17 4, and 17 9 per 1000 in the three preceding weeks fell in the week under notice to 17 6 per 1000 of their aggregate population estimated at 1,148,468 persons at the middle of last year During the first four weeks of the current quarter the mean annual death rate in these town averaged 18 5, against corresponding rates of 14 1 and 15 1 per 1000 in the English and Scotch towns respectively The death rate during the week under review was equal to 19 5 in Dublin (against 13 9 in London and 14 4 in Glasgow), 15 0 in Belfast, 27 2 in Cork, 13 9 in Londonderry, 17 6 in Limerick, and 11 4 in Waterford while in the 13 smaller towns the mean rate was 16 7 per 1000

The 388 deaths from all causes were 7 fewer than the number in the previous week, and included 27 which were referred to the principal epidemic diseases, against 30 and 32 in the two preceding weeks Of these 27 deaths, 8 resulted from infantile diarrhœal diseases, 7 from whooping-cough, 6 from measles, 4 from enteric fever, and 2 from diphtheria, but not one from scarlet fever or from small pox The annual death rate from these diseases was equal to 1 2 against corresponding rates of 0 9 and 1 5 per 1000 in the English and Scotch towns respectively The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 8, 6, and 8 in the three preceding weeks were again 8 in the week under notice, and included 6 in Dublin The deaths attributed to whooping-cough, which had been 4, 5, and 8 in the three preceding weeks, numbered 7, of which 3 were recorded in Belfast and 2 in Portadown The fatal cases of measles, which had been 9 14, and 9 in the three preceding weeks fell to 6 and included 3 in Belfast Of the 4 deaths from enteric fever, 3 were registered in Cork and 1 in Dublin, while those from diphtheria occurred in Dublin and Belfast

The deaths referred to diseases of the respiratory system, which had declined from 147 to 63 in the four preceding weeks, were again 63 in the week under notice, and were 96 below the number registered in the corresponding week of last year Of the 388 deaths from all causes, 132, or 34 per cent occurred in public institutions and 8 resulted from violence The causes of 19 or 4·9 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest, and included 7 in Dublin and 3 in Limerick In the large English towns the proportion of uncertified causes did not exceed 0·9 per cent

---

UNIVERSITY OF SHEFFIELD - The Council, at its meeting on Feb 7th appointed Dr Arthur J Hall senior physician to the Sheffield Royal Hospital, to the Professorship of Medicine, in succession to Dr Duncan Burgess

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments have been notified — Surgeons K. H Hale to the *Maidstone*, and L B Stringer (temp) to the *Victory*, for Haslar Hospital Temporary Surgeons T Beaton to the *Pembroke*, additional for Chatham Hospital, H S Sington to the *Pembroke* C E Kindersley to the *Victory*, F L Cassidi to the *Vivid*, all additional for Chatham, Haslar, and Plymouth Hospitals, respectively, and H E Hewat to the *Euryal*

ARMY MEDICAL SERVICE

Lieutenant-Colonel C W Profeit to be temporary Colonel whilst an Assistant Director of Medical Services

ROYAL ARMY MEDICAL CORPS

The undermentioned Majors are retained on the Active List and to be supernumerary E E Powell and W A S J Graham

The undermentioned temporary Captains relinquish their commissions E L Middleton, J Ewing, and H Munro

The undermentioned to be temporary Captains Captain B G Elliott, The East Lancashire Regiment, Territorial Force, Captain J M D Scott, South African Medical Corps, Temporary Lieutenant R B Taylor, Temporary Captain S J Scott, from Princess Victoria's (Royal Irish Fusiliers) G Graham, L F Jones, C A.M C, and J A Hunt, C A.M C,

The undermentioned temporary Lieutenants to be temporary Captains —J D Finlay, W Winslow, A C D Firth, C H. Philips, T J Kelly, C J H Sharp, C F O White, E S Dixon, W Pritchard Airey, J Morrison, J C Dunn, W C S Wood, D Watson, G A Maling, V C L A. P Burt, S R Mackenzie, A Ryland C J Glasson, H W Doll, J Tate, W A Taylor, A W H Donaldson, J F Venables, E B Sunderland, C W Roe, F C Greig, J P Blockley, D W Beamish, W Leslie, J Parker, C C Beatty W A Brown, R H Fothergill D M MacManus, U J Bourke, H N Everard, H. S de Boer G A C Gordon, D Green, C Banting, R W Murphy, W G Ridgway, R A Wright, B M Collard, T J R Maguire, B H Barton, G F Barr, P H MacDonald, C L Wigan, J C Robb, W S Heron, R MacGrath, C N Vaisey L A. Drake H J Cotter, T S Goodwin, J S Prentice, W J A B Wishart, W S Lindsay, G Davidson, G T Cregan, H S Stockton, C de C Pellier, and J R Lee

Temporary Honorary Lieutenant O G Morgan to be temporary Honorary Captain whilst serving with No 9 British Red Cross (Duchess of Sutherland's) Hospital

Lieutenant M W Paterson to be Captain

The undermentioned temporary Honorary Lieutenants to be temporary Lieutenants —E J Clark, W J Pearson, and C F Maclachlan

The undermentioned to be temporary Lieutenants — The undermentioned to be temporary Lieutenants — W H Broughton, M Campbell, W Paul, C Cooper, W H Broughton, M Campbell, W Paul, C Cooper, R A. Warters, G FitzGerald A. D Moffat, J J W Speedy, R A. Warters, G FitzGerald A. D Moffat, J J W Speedy, R E Illingworth, A. D Hunt, D R Taylor, A W Clarke, R E Illingworth, A. D Hunt, D R Taylor, A W Clarke, E L Christoffelsz Mather, A C Tait, C W C Robinson, N A. Boswell, W D D J G M Molony, A D Buchanan, R Montgomery, L T Small, R M Hewitt J P Fairley, C S Rivington, W M Giles, H C Fox, E W Martin, W B Mercer, R R Muirhead, E H Cameron J Bain, F W Craig, Watts, C M G Elliott, N Grace, S Stockman, F J Eagar, P G J Oag, A McL Pilcher, H N Ingham, A H Donaldson and J McF Temple, J F St J Annesley, Grier

The undermentioned to be Honorary Lieutenants — W R White-Cooper and H W Bennett

The undermentioned temporary Lieutenants relinquish their commissions —C A Smallhorn H W Fankhausen S Reader, J N G W McMorris, F L Gill P Steele F J Browne, A E Townley, H F Smith, W M Thomas A. F G Codd, H Armstrong G De P D'Amico, R N Geach, G O Jacobsen, M P Thomas, G M De Vines and J R McGilvray

INDIAN MEDICAL SERVICE

Temporary Lieutenant J McIntire Falkiner to be temporary Captain

A. C Dutt, R N Kapadia, N B Aich S C Sen, P R Vakil, and B Rai have been granted the temporary rank of Lieutenant

The King has approved the retirement of Lieutenant Colonels W R Clark G S Thomson and C G Webster and Majors W G Richards and W C Long

SPECIAL RESERVE OF OFFICERS

Royal Army Medical Corps

The undermentioned Lieutenants to be Captains W J Dowling A R F Clarke A J Horne N L Reis C E H Gater D C Pim F R S Shaw R G Blair F R H Mollan G Stanton J D Proud T W E Elliott J O S Beveridge, A J Beveridge S D Lodge C H Brennan

E N H Gray, J A Musgrave, T McClurkin, T R S Cumming, D H Murray, W A Thompson, J W B Foley, D Dempster, and T N Barkley

Lieutenant (on probation) T E B Beatty is confirm his rank

Cadet W L A. Harrison, London University Contin O T C, to be Lieutenant

TERRITORIAL FORCE

Army Medical Services

Captain A Baxter, from Attached to Units other th Medical Units, to be Deputy Assistant Director of Me Services, Mounted Division

J Ewing (late Captain, West Riding Field Ambula and late temporary Captain, R A M C) to be Captain Deputy Assistant Director of Medical Services

Royal Army Medical Corps

Welsh Border Mounted Brigade Field Ambulance J B Yeoman, from Army Medical Services to be Major

Highland Field Ambulance Lieutenant J A Sellar to Captain

South Midland Field Ambulance Lieutenant E J Groves is restored to the establishment

London General Hospital J A Willett to be L tenant

Southern General Hospital Lieutenants C B Hawth and J Millard to be Captains

West Lancashire Casualty Clearing Station Lieut T Aspinall to be Captain

North Midland Casualty Clearing Station N H Hill to Lieutenant

Yorkshire Mounted Brigade Field Ambulance L tenant A M Deane to be Captain

West Lancashire Field Ambulance Captain E W from Attached to Units other than Medical Units to Captain

London (City of London) Sanitary Company To be L tenants J Teare and F E W Rogers

London Sanitary Company To be Lieutenants S Summ son and E P Wheeler

Attached to Units other than Medical Units —Majo Beard resigns his commission on account of ill he Lieutenants S Hughes and F J Davidson to be Captain

DEATHS IN THE SERVICES

Lieutenant-Colonel Thomas Michael O'Brien A (retired), recently at his residence in Exeter He joined Army Medical Service in 1858, and shortly afterwards to India, and, except for two short periods of time, rema in India until 1887 In 1888 he was appointed chief me officer of the Exeter military hospitals He retired in but still continued to reside in Exeter, where he numerous friends and was highly respected and esteem He leaves a widow and married daughter

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS

First place is given in the January issue of this journ a long and excellently illustrated article by Surgeon Gen Sir George Makins on a Study of 111 Cases of Perfora Wounds of the Gastro-intestinal Canal which occur amongst a consecutive series of 202 perforating wound the abdomen in which the presence of visceral injury certain The Toxicity of Emetine is the title of a joint p by Temporary Lieutenant Colonel Andrew Balfour and Frank Lee Pyman, D Sc, Ph D, in which the c clusion is drawn that more information on the subj is required and the hope is expressed that medical offic serving with the Mediterranean Expeditionary Force have administered emetine in cases of amoebic dysent will not hesitate to place their experiences on rec Captain A. W Ormond R A M C (T), and Major A F He describe the treatment of "Concussion Blindness hypnosis good results having been obtained and Cap T H Just contributes a survey of the results obtained dur six months of enteric bacteriology at a general hospital a paper on a Classification of Meningococci Based on Gr Agglutination obtained with Monovalent Immune Lab Sera Captain A W M Ellis suggests that in the treatme cerebro-spinal fever better results might be obtained an exact knowledge of the adequacy of serum tre gained, if monovalent horse serum of appropriate type employed in place of the polyvalent sera Meningo Carriers are discussed in a joint paper by Cap Colebrook and Lieutenant H H Tanner while Medium for the Identification of the Meningococci Sugar Reactions forms the subject of a report to the Me Research Committee by Mr H W C Vines B A

THE RUSSIAN ORDER OF ST ANNE

Temporary Surgeon Thomas S ratford has received the Royal Licence and Third Class of the Order of St Anne with swords been conferred upon him by the Emperor of Russia nition of valuable services rendered

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census 7301 births and 5098 deaths were registered during the week ended Saturday, Feb 5th The annual rate of mortality in these towns which had been 13·9, 14 2, and 14·0 per 1000 in the three preceding weeks, rose in the week under notice to 14 7 per 1000 of their aggregate population, estimated at 18,136,180 persons at the middle of the year 1914 During the first five weeks of the current quarter the mean annual death rate in these towns averaged 14 2, against a corresponding rate of 13 6 in London The annual death rate last week ranged from 3 4 in Ilford, 4·9 in Swindon 8 2 in Hornsey, in East Ham, and in Newport (Mon), 8·6 in Northampton, and 9 1 in Bournemouth to 20 6 in Liverpool 20 8 in Burnley, 21 1 in South Shields, 22 2 in Dewsbury, and 24 3 in West Hartlepool

The 5098 deaths from all causes were 238 in excess of the number in the previous week and included 340 which were referred to the principal epidemic diseases, against 305 and 314 in the two preceding weeks Of these 340 deaths, 104 resulted from whooping-cough 70 from infantile diarrhœal diseases, 63 from diphtheria 62 from measles, 28 from scarlet fever 12 from enteric fever, and 1 from small pox. The death rate from these diseases was equal to 1·0, against 0 9 per 1000 in each of the two preceding weeks The deaths attributed to whooping cough which had been 78, 74, and 80 in the three preceding weeks, further rose to 104, and included 28 in London, 10 in Liverpool, 9 in Birmingham, 5 each in Leicester and Manchester, and 4 each in West Ham, Coventry and Leeds. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 60, 60 and 68 in the three preceding weeks, further rose to 70, of which 17 were recorded in London, 4 each in Birmingham and Sheffield and 3 each in Stoke-on Trent, Leeds and Liverpool The fatal cases of diphtheria which had been 84, 79 and 70 in the three preceding weeks, further fell to 63, 16 deaths were registered in London, 4 each in Portsmouth, Plymouth and Liverpool, and 3 each in Bristol, Stoke-on Trent Birmingham and St Helens The deaths attributed to measles, which had declined from 81 to 62 in the four preceding weeks, were again 62 last week and included 8 in London, 6 each in Nottingham, Stockport, and Burnley, and 5 each in Bristol, Leicester, and Leeds The deaths referred to scarlet fever, which had been 23 10 and 25 in the three preceding weeks, rose to 28, of which 7 occurred in London, 4 in Stoke-on Trent and 2 each in Manchester Sheffield and Newcastle-on Tyne The fatal cases of enteric fever which had been 9 in each of the three preceding weeks rose to 12 and included 3 in Wigan and 2 in Reading The death from small pox was registered in Salford

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2224, 2257, and 2189 at the end of the three preceding weeks, further fell to 2153 on Saturday last, 253 new cases were admitted during the week against 244, 286 and 260 in the three preceding weeks These hospitals also contained on Saturday last 1557 cases of diphtheria 143 of whooping-cough, 48 of enteric fever and 47 of measles, but not one from small pox The 1206 deaths from all causes in London were 4 in excess of the number in the previous week, and corresponded to an annual death rate of 13·9 per 1000 The deaths referred to diseases of the respiratory system, which had been 264 254, and 231 in the three preceding weeks, fell to 225 in the week under notice, and were 272 below the number registered in the corresponding week of last year

Of the 5093 deaths from all causes in the 96 towns, 191 resulted from violence and 377 were the subject of coroners' inquests while 1415 occurred in public institutions The causes of 58, or 1 1 per cent of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in Leeds Bristol West Ham Bradford Hull, Newcastle-on Tyne and in 67 other smaller towns Of the 58 uncertified causes 13 were registered in Liverpool 10 in Birmingham 3 each in Gateshead and London and 2 each in 10 other towns

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2,355 300 persons at the middle of this year 1034 births and 606 deaths were registered during the week ended Saturday Feb 5th The annual rate of mortality in these towns which had been 15 [illegible] 14 [illegible] and 14 6 per 1000 in the three preceding weeks fell to 13 [illegible] per 1000 in the week under notice During the first five weeks of the current quarter the mean annual death rate in these towns averaged 14 7, against a corresponding rate of 14 2 per 1000 in the large English towns Among the several towns the death rate last week ranged from 2 3 in Clydebank, 9·9 in Motherwell, and 11 4 in Edinburgh, to 19·4 in Paisley 20·1 in Greenock, and 21 5 in Perth

The 606 deaths from all causes were 52 fewer than the number in the previous week and included 50 which were referred to the principal epidemic diseases, against 43 and 59 in the two preceding weeks Of these 50 deaths, 22 resulted from measles 14 from diphtheria, 7 from scarlet fever, 6 from infantile diarrhœal diseases, and 1 from enteric fever, but not one from whooping-cough or from small pox. The annual death rate from these diseases was equal to 1 1, against a corresponding rate of 1·0 per 1000 in the large English towns The deaths attributed to measles which had been 23 19, and 29 in the three preceding weeks, fell to 22 and included 6 in Greenock, 5 in Glasgow, 4 in Coatbridge, and 2 each in Edinburgh and Ayr The deaths referred to diphtheria which had been 13, 8, and 15 in the three preceding weeks, were 14 last week, of which 5 occurred in Glasgow and 4 in Edinburgh The fatal cases of scarlet fever, which had declined from 18 to 7 in the four preceding weeks, were again 7 last week, and included 5 in Glasgow The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 13, 4, and 13 in the three preceding weeks, fell to 6 of which 2 occurred in Glasgow The fatal case of enteric fever was recorded in Dundee

The deaths referred to diseases of the respiratory system, which had been 114, 92, and 97 in the three preceding weeks, fell to 73 in the week under notice, and were 229 below the number registered in the corresponding week of last year The deaths from violence numbered 23, against 37 and 23 in the two preceding weeks

HEALTH OF IRISH TOWNS

In the 19 town districts of Ireland, with populations exceeding 10 000 persons at the last Census, 530 births and 388 deaths were registered during the week ended Saturday, Jan 29th The annual rate of mortality in these towns, which had been 21·0, 17 4, and 17 9 per 1000 in the three preceding weeks fell in the week under notice to 17 6 per 1000 of their aggregate population estimated at 1,148,468 persons at the middle of last year During the first four weeks of the current quarter the mean annual death rate in these town averaged 18 5, against corresponding rates of 14 1 and 15 1 per 1000 in the English and Scotch towns respectively The death-rate during the week under review was equal to 19 5 in Dublin (against 13·9 in London and 14 4 in Glasgow), 15·0 in Belfast, 27 2 in Cork, 13 9 in Londonderry, 17 6 in Limerick, and 11 4 in Waterford while in the 13 smaller towns the mean rate was 16 7 per 1000

The 388 deaths from all causes were 7 fewer than the number in the previous week, and included 27 which were referred to the principal epidemic diseases, against 30 and 32 in the two preceding weeks Of these 27 deaths, 8 resulted from infantile diarrhœal diseases, 7 from whooping-cough, 6 from measles, 4 from enteric fever, and 2 from diphtheria, but not one from scarlet fever or from small pox. The annual death rate from these diseases was equal to 1 2 against corresponding rates of 0·9 and 1 5 per 1000 in the English and Scotch towns respectively The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 8, 6 and 8 in the three preceding weeks, were again 8 in the week under notice, and included 6 in Dublin The deaths attributed to whooping-cough, which had been 4 5 and 8 in the three preceding weeks numbered 7, of which 3 were recorded in Belfast and 2 in Portadown The fatal cases of measles which had been 9 14, and 9 in the three preceding weeks fell to 6 and included 3 in Belfast Of the 4 deaths from enteric fever, 3 were registered in Cork and 1 in Dublin while those from diphtheria occurred in Dublin and Belfast

The deaths referred to diseases of the respiratory system which had declined from 147 to 63 in the four preceding weeks, were again 63 in the week under notice, and were 96 below the number registered in the corresponding week of last year Of the 388 deaths from all causes, 132 or 34 per cent, occurred in public institutions and 8 resulted from violence The causes of 19 or 4·9 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest and included 7 in Dublin and 3 in Limerick, in the large English towns the proportion of uncertified causes did not exceed 0·9 per cent

ALBUMINURIC RETINITIS IN EPIDEMIC (ACUTE) NEPHRITIS

To the Editor of THE LANCET

SIR,—The war has raised many problems, some new, others old but brought into fresh prominence Among these is that of acute nephritis It might have been expected that acute nephritis would be common among those who had passed through the cold exposure of trench life, yet the war has conclusively shown that cold and exposure as such are at the most contributory causes only The outbreak in the warm weather, when the winter was past, was so extensive that it deserved the name of epidemic nephritis given to it, though investigation has so far failed to track the cause down to any recognisable infection or germ The study of a series of these cases at St Bartholomew's Hospital has led to most interesting results in the capable hands of Dr W Langdon Brown and his co workers

One special branch of the subject has recently been dealt with in this journal[1] by Mr R Foster Moore, in an article entitled "Renal Retinitis in Epidemic Nephritis" The paper is a valuable one, but its value would have been greater if Mr Foster Moore had carefully defined what he meant by chronic nephritis and by renal retinitis

Chronic nephritis—Acute nephritis if it lasts some time leads to the large white kidney which is commonly called *chronic parenchymatous nephritis*, and in this condition may persist for months[2] Whether it ever passes into the contracted form or not is a question which need not be discussed here The *contracted-form* certainly in the vast majority of cases gives no history of acute nephritis, and is probably essentially a degenerative and not a post inflammatory condition. Bright in his original papers distinguished sharply between the two forms, and stated that he was unable to satisfy himself that there was any connexion between them Wilks, with all his experience, said that he had failed to establish any relation between them, and held them to be different diseases My own experience has led me to the same conclusion Proof must depend upon clinical evidence and this is lacking Chronic nephritis is often used to cover both the groups, and confuses two conditions which are essentially distinct—viz., parenchymatous nephritis of some duration, i e, in its later stages, and granular kidney

Albuminuric retinitis—This also exists in two forms which ought to be sharply distinguished from one another I named them some years ago the exsudative and the degenerative form They are quite distinct from one another in their ophthalmoscopic appearances, in their pathology, as well as in their clinical significance

The *exsudative form* is the same as that usually understood by the term acute optic neuritis, and is like that seen with a cerebral tumour It may occur in acute or chronic parenchymatous nephritis, and may then resolve and disappear if the nephritis recover It may also occur in granular kidney, when it is most unlikely to resolve because it is rarely if ever seen, except in the terminal stage and when the end is near

The *degenerative form* presents the glistening white patches round about the yellow spot especially, which are so characteristic of albuminuric retinitis It is pathognomonic of granular kidney, for it occurs in no other disease It is the result of permanent degenerative changes in the retina and never disappears It may in the later stages of granular kidney have grafted on it, or added to it, the exsudative form but the two forms are even then independent of one another

The statements made about albuminuric retinitis in books are hopelessly contradictory, and this is not surprising, for with two forms of chronic nephritis distinct from one another and two forms of albuminuric retinitis also distinct from another there is plenty of room for divergence or contradiction if the distinctions are not made and not clearly observed

When equally competent observers contradict one another on questions of fact it must follow either that they are dealing not with the same but with different facts, or that the facts are not simple but complex and coloured by different theories, or that the same words are used to denote different things The two terms which lead to all this confusion are chronic nephritis and albuminuric retinitis If these are properly defined and the distinctions strictly observed all the apparent contradictions can be reconciled.

It is now possible to put Mr Foster Moore's observations into the category to which they rightly belong It is clear 1 That all the cases he deals with are acute nephritis Even what he calls chronic nephritis is merely acute nephritis which has lasted somewhat longer than the others, and the pathological condition is that of chronic parenchymatous nephritis or the large white kidney 2 That the form of albuminuric retinitis met with in his cases is of the exsudative type

Thus defined Mr Foster Moore's paper has a greater value than he claims for it It shows first that albuminuric retinitis in one of its forms occurs in acute nephritis, on which he expressed a somewhat uncertain opinion There can be no doubt of the fact, in spite of the statement he quotes on Sir Wilmot Herringham's authority I have seen many instances of it myself, and recorded some in my Lettsomian lectures as long ago as 1900 Not only does it occur, but it is not altogether uncommon Mr Foster Moore met with it in 4 2 per cent of the 119 cases he observed It is most likely to be met with in cases of some standing—eight or nine weeks he seems to regard as making the disease chronic, but such a duration is really short for many cases of acute nephritis which get perfectly well last as long as this and much longer, too Nor is mere duration of itself sufficient, for albuminuric retinitis may remain absent in cases of much longer duration He refers himself to one of 20 weeks duration Three out of the five cases he quotes were severe, for they had uræmia

To sum up the facts as my experience leads me to do, I should say 1 Albuminuric retinitis may occur and is not rare in acute nephritis 2 It is of the exsudative type 3 It is an indication of the severity of the case, and though more likely to be found in cases of some duration it may be present quite early if the case be severe or remain absent throughout if the case be mild 4 In any case, if the nephritis resolve it may completely disappear and leave no defect of vision behind 5 The statement that it is toxic in origin is probably correct

---

[2] THE LANCET Nov 20th 1915 p 1123.

Mr Foster Moore's observations are a distinct contribution to the subject, and so far as acute nephritis is concerned confirm the views I expressed definitely in my Lettsomian lectures of 1900

On consulting recently a large encyclopædia of ophthalmology, published only two years ago, the chapter on albuminuric retinitis is as vague and unconvincing as ever, and the important distinctions I have mentioned are not even referred to, so that no excuse is necessary for reiterating what I have so often written —I am, Sir, yours faithfully,

INVERSION OF THE PELVIC BONES

To the Editor of THE LANCET

SIR,—In your issue of Feb 5th Professor G Elliot Smith makes some critical remarks on my paper on Inversion of the Ilium and Sacrum and Ischium and Pubes as causes of deformities of the female pelvis[1] I hope I may be allowed by your courtesy to reply to his remarks, which are as follows —

> Dr D Berry Hart s memoir (see THE LANCET, Jan 29th, p 255) does not warrant the assumption that the inversion of the pelvic bones as a cause of trouble in the female is a pathological condition newly discovered by him Dr Douglas E Derry, when working in the Medical School in Cairo, was the first to give an adequate explanation of the significance of the preauricular grooves in the female os innominatum, and both he and Professor Wood Jones called attention to cases in ancient Nubian skeletons where inversion of the pelvic bones was a cause of deformity In several cases they found the fœtal head impacted in such pelves

This account is incorrect In the first place, Zaaijer in 1866 drew attention to the sulcus preauricularis, and Dr Derry says "Another feature of considerable significance in determining the sex of a given bone may be found in the groove or sulcus first described by Zaaijer in 1866" It is not found constantly and is of secondary importance, although Professor Wood Jones says "it is by far the most valuable sexual indication we have"[2] The important means of sexing pelvis is the sacrosciatic notch, and on this I say in my paper, "General anatomists have, however, drawn attention to special differences between the male and female ilium, since it is of importance, as Elliot Smith and Wood Jones have shown in archæological work, to determine the sex from an isolated ilium" I then give the points as to the sacrosciatic notch In regard to obstetricians I criticise them and myself, of course, for neglecting these questions, and praise the general anatomists for their work in regard to them What I claim to have shown is that in certain deformed pelves the deformity is due to inversion of the ilium or of the ischium and pubes On this Professor Elliot Smith says as to the cases where the women had died in labour "In every one of these cases the pelvis was of abnormal form and most of them exhibited a sex contradiction"[3] Nowhere, so far as I am aware, is inversion spoken of The terms 'sex contradiction" is incorrect, as the sex gland is the criterion of sex, whereas the pelvis is part of the sex ensemble I must finally ask Professor Elliot Smith to quote any passages in my paper where I have claimed any originality as to the facts of the sacrosciatic notch and sulcus preauricularis He might also quote from his monograph any statement he makes as to his cases of deformed pelves being termed "inversion" He uses the term "sex contradiction" in it and "inversion" for the first time in his letter

I am, Sir, yours faithfully,

D BERRY HART

FUNCTIONAL NERVOUS DISEASES

To the Editor of THE LANCET

SIR,—I read with pleasure Captain William Brown's logical and temperate letter published under this heading in your issue of Jan 29th Those who have followed the modern developments of the psycho analytic (or, as Captain Brown prefers to call it, the autognostic) method of treatment of functional nervous disease must realise that the theory of Freud is too limited to account for all the observed facts, but this should not in itself make this method of treatment disreputable As practised now, psycho analysis is a careful inquisition into the mental history and processes of a patient, by means of free association, word association, and dream analysis, with the object of finding out whether there is or is not anything in these processes that has a bearing on his present disability If such a factor is discovered, the thorough understanding by the patient of its association with the nervous manifestation from which he suffers has a striking effect as far as the relief of this manifestation is concerned

There are at present three chief methods by means of which functional nervous manifestations may be attacked, these are—psycho analysis, hypnosis, and isolation My own experience, as officer in charge of the nerve hospitals in the 2nd Western Command, is limited to the first and third of these three methods, but the value of hypnosis has been convincingly demonstrated quite recently in your journal by Major C S Myers

As regards psycho analysis, my experience is that improvement in the patient's condition is brought about in the majority of cases so treated, but that there is a strong tendency to relapse The treatment has to be persisted in for a very considerable time, and even then, after an apparent cure, a subsequent relapse is not infrequent There are, however, a certain number of patients that are not improved at all by this method, though this number does not form a large proportion of the cases treated

In the case of treatment by isolation I find that the results are of the "all or nothing" category if the patient reacts at all the improvement is more lasting, but the number of patients that do improve is less than in the case of the psycho analytic method

It seems to me that the point to which attention ought to be devoted now is the indications by means of which we may come to a decision as to which method of treatment is likely to give the best result in any particular case In the present state of our knowledge this is not at all an easy decision to form, and the difficulty is by no means lessened by adopting a hostile attitude towards any one method The mental configurations of a large number of patients must of necessity be diverse, and it is only reasonable to assume that these three methods of treatment possess different values in different cases

I am, Sir, yours faithfully,

DONALD E CORE,

Captain R A.M C. (T.F) Honorary Physician to the Ancoats Hospital Manchester

2nd Western General Hospital Feb 1st 1916

ALBUMINURIC RETINITIS IN EPIDEMIC (ACUTE) NEPHRITIS

To the Editor of THE LANCET

SIR,—The war has raised many problems, some new, others old but brought into fresh prominence Among these is that of acute nephritis It might have been expected that acute nephritis would be common among those who had passed through the cold exposure of trench life, yet the war has conclusively shown that cold and exposure as such are at the most contributory causes only The outbreak in the warm weather, when the winter was past, was so extensive that it deserved the name of epidemic nephritis given to it, though investigation has so far failed to track the cause down to any recognisable infection or germ The study of a series of these cases at St Bartholomew's Hospital has led to most interesting results in the capable hands of Dr W Langdon Brown and his co workers

One special branch of the subject has recently been dealt with in this journal[1] by Mr R Foster Moore, in an article entitled "Renal Retinitis in Epidemic Nephritis" The paper is a valuable one, but its value would have been greater if Mr Foster Moore had carefully defined what he meant by chronic nephritis and by renal retinitis

Chronic nephritis—Acute nephritis if it lasts some time leads to the large white kidney which is commonly called *chronic parenchymatous nephritis*, and in this condition may persist for months[2] Whether it ever passes into the contracted form or not is a question which need not be discussed here The *contracted form* certainly in the vast majority of cases gives no history of acute nephritis, and is probably essentially a degenerative and not a post inflammatory condition Bright in his original papers distinguished sharply between the two forms, and stated that he was unable to satisfy himself that there was any connexion between them Wilks, with all his experience, said that he had failed to establish any relation between them, and held them to be different diseases My own experience has led me to the same conclusion Proof must depend upon clinical evidence and this is lacking Chronic nephritis is often used to cover both the groups, and confuses two conditions which are essentially distinct—viz., parenchymatous nephritis of some duration, i e , in its later stages, and granular kidney

Albuminuric retinitis—This also exists in two forms which ought to be sharply distinguished from one another I named them some years ago the exsudative and the degenerative form They are quite distinct from one another in their ophthalmoscopic appearances, in their pathology, as well as in their clinical significance

The *exsudative form* is the same as that usually understood by the term acute optic neuritis, and is like that seen with a cerebral tumour It may occur in acute or chronic parenchymatous nephritis, and may then resolve and disappear if the nephritis recover It may also occur in granular kidney, when it is most unlikely to resolve because it is rarely if ever seen, except in the terminal stage and when the end is near

The *degenerative form* presents the glistening white patches round about the yellow spot especially, which are so characteristic of albuminuric retinitis It is pathognomonic of granular kidney, for it occurs in no other disease It is the result of permanent degenerative changes in the retina and never disappears It may in the later stages of granular kidney have grafted on it, or added to it, the exsudative form, but the two forms are even then independent of one another

The statements made about albuminuric retinitis in books are hopelessly contradictory, and this is not surprising, for with two forms of chronic nephritis distinct from one another and two forms of albuminuric retinitis also distinct from another there is plenty of room for divergence or contradiction if the distinctions are not made and not clearly observed

When equally competent observers contradict one another on questions of fact it must follow either that they are dealing not with the same but with different facts, or that the facts are not simple but complex and coloured by different theories, or that the same words are used to denote different things The two terms which lead to all this confusion are chronic nephritis and albuminuric retinitis If these are properly defined and the distinctions strictly observed all the apparent contradictions can be reconciled.

It is now possible to put Mr Foster Moore's observations into the category to which they rightly belong It is clear 1 That all the cases he deals with are acute nephritis Even what he calls chronic nephritis is merely acute nephritis which has lasted somewhat longer than the others, and the pathological condition is that of chronic parenchymatous nephritis or the large white kidney 2 That the form of albuminuric retinitis met with in his cases is of the exsudative type

Thus defined Mr Foster Moore's paper has a greater value than he claims for it It shows first that albuminuric retinitis in one of its forms occurs in acute nephritis, on which he expressed a somewhat uncertain opinion There can be no doubt of the fact, in spite of the statement he quotes on Sir Wilmot Herringham's authority I have seen many instances of it myself, and recorded some in my Lettsomian lectures as long ago as 1900 Not only does it occur, but it is not altogether uncommon Mr Foster Moore met with it in 4 2 per cent of the 119 cases he observed It is most likely to be met with in cases of some standing—eight or nine weeks he seems to regard as making the disease chronic, but such a duration is really short, for many cases of acute nephritis which got perfectly well last as long as this and much longer, too Nor is mere duration of itself sufficient for albuminuric retinitis may remain absent in cases of much longer duration He refers himself to one of 20 weeks duration Three out of the five cases he quotes were severe, for they had uræmia

THE INCOME-TAX AND GRATUITIES TO TEMPORARY LIEUTENANTS, R A M C

To the Editor of THE LANCET

SIR,—As is well known, certain gratuities and bonuses are granted by the War Office to temporary lieutenants of the Royal Army Medical Corps after 12 months' service, and a question has arisen as to whether such grants become taxable as "income" under the present Finance Acts As the matter was one which was by no means clear and was of much interest to the military members of our profession, I applied to Sir Henry Craik, M P, K C B, the Parliamentary representative for Aberdeen and Glasgow Universities, for his valuable aid in putting a question to the Treasury through its Parliamentary Secretary, Mr Montagu The reply, written and addressed to Sir Henry Craik, is, I take it, of sufficient importance to be recorded in your journal, and I accordingly append it —

> I return herewith the letter from the Medical Defence Union which you handed to me respecting bonuses and gratuities given to temporary lieutenants, R A M C It seems probable that these bonuses and gratuities are generally given, under the officer's contract, for satisfactory service At any rate there is no reason to doubt that they are given in respect of and in consideration of his services and as such they will be liable to income tax I may perhaps add that firstly an officer in the Royal Army Medical Corps will come under the liberal relief provisions of Section 25 (1) of the Finance (No 2) Act, 1915, if his total income does not exceed £300, and secondly, under Section 13 (1) of the Finance Act, 1914 (Session 2), and Section 20 of the Finance Act, 1915, he will only bear tax in respect of the practice he has given up on the basis of the actual profits (if any) of the year, instead of on the average of the past three years

This will effectively clear the issues involved and make the position no longer doubtful

I am, Sir, yours faithfully,
A G BATEMAN,
General Secretary Medical Defence Union
4, Trafalgar square W C Feb 4th 1916.

AMMONIA AS AN ENEMA

To the Editor of THE LANCET

SIR,—May I draw your readers' attention to the effectiveness of an ammonia enema in the treatment of post operative ileus and intestinal paresis This sequela of an abdominal operation all have found to be most distressing to the patient, while it is exasperating to the surgeon, and in extreme cases even dangerous to the patient's life I understand that at the front it has proved frequently a fatal complication of operations for abdominal wounds

The prescription is liq ammon fort 1 dr, water 1 pint, administered as an enema, its effect is greatly enhanced by a hypodermic of pituitrin extract 1 c c half an hour previously This treatment is sure to result in a good motion and discharge of excessive flatus, and again and again I have found it to act where the ordinary enemata, turpentine, eserine, &c, had failed Two words of warning I would give—namely that if used frequently, or if used in greater strength than I suggest, injury to the rectal mucous membrane is liable to take place On two occasions the daily administration of the enema for three consecutive days resulted in a certain amount of rectal hæmorrhage On another occasion the mistake of a nurse in putting in too much ammonia gave the patient a very painful septic colitis lasting for a week

My excuse in writing about this is that although I do not claim originality I have not been able to find in any text book any mention of ammonia as an enema, nor have I ever met anyone in England who ever heard of it Yet I am convinced of its importance —I am Sir, yours faithfully,

T A BLACK, M B,
Resident Medical Officer Barnes Convalescent Hospital Cheadle
Feb 1st 1916

MATRICULATION AT THE UNIVERSITY OF MANCHESTER

To the Editor of THE LANCET

SIR,—In the report of the Committee of Management to the Conjoint Examining Board of the Royal Colleges, as well as in the report of the Comitia of the Royal College of Physicians, it has been stated that Latin is no longer a compulsory subject in the entrance examination to the Faculty of Medicine in the University of Manchester

I should be glad if you would allow me to correct this misunderstanding The University of Manchester has not modified the matriculation requirements —I am, Sir, yours faithfully,

G ELLIOT SMITH,
Dean of the Faculty of Medicine
University of Manchester
Feb 8th 1916

⁂ The excerpt from the report of the Committee of Management, in our account of the Comitia of the Royal College of Physicians of London, was an accurate reproduction of the words of the report —ED L

THE TREATMENT OF WHOOPING COUGH

To the Editor of THE LANCET

SIR,—I have read with interest the annotation on whooping cough in THE LANCET of Jan 29th. I vividly remember the sufferings of my own children several years ago from this horrible disease, and the heart breaking failure of one drug after another to even more than very slightly relieve the symptoms Practically every one of those mentioned was tried under the advice of a distinguished colleague From that time until a year ago I have as signally failed During the early part of 1915 several cases came under my notice and I painted the children's chests front and back with a mixture of cantharides, croton oil, and almond oil The result was most gratifying Every case was aborted within 14 days The following is a good formula —

℞	Ol croton	ʒ i
	Cantharadini	gr iii
	Acidi acet fort	ʒ i
	Ol amygdal dulc	ad ℥ viii

The painting was carried out weekly and occasioned no distress I am, Sir, yours faithfully,

W J MIDELTON
Bournemouth Feb 1st 1916

SODIUM GYNOCARDATE IN LEPROSY —Mr W Martindale writes to us, pointing out that palmitic acid is one of the natural constituents of genuine chaulmoogric acid, and cannot be termed "an impurity," to use Sir Leonard Rogers's phrase in our columns last week Samples may certainly vary in the amount contained

THE SOUTH AFRICAN HOSPITAL. — Lord Gladstone writing to the press on behalf of the South African Hospital and Comforts Fund has intimated that a programme has now been drawn up providing for a completely equipped hut hospital in Richmond Park As far as possible the medical and nursing staff will be obtained from South Africa The office address of the fund is 2 London Wall Buildings E.C

Obituary

CHARLES STONHAM, F.R C S ENG, C M G,

COLONEL, A.M.S SENIOR SURGEON TO WESTMINSTER HOSPITAL.

Charles Stonham was born at Maidstone in 1858 He was educated at King's School, Canterbury, and went to University College Hospital Medical School, where he gained the Atchison Scholarship in 1881 In a successful academic career he took gold medals in surgery and obstetric medicine at the University of London, becoming an F.R C S in 1884 He was a man of great natural ability, who profited to the full from the teaching given by the distinguished men then on the staff of the hospital Marcus Beck was the great exemplar upon whom he modelled himself, whilst Berkeley Hill gave him an inclination for his particular line of practice In addition, as obstetric assistant under Sir John Williams he obtained a good introduction to abdominal surgery His connexion with University College Hospital continued for some years, he held successively all the resident posts, was senior demonstrator of anatomy in the medical school, and whilst he served as curator of the pathological museum he worked with great zeal at a descriptive catalogue of the surgical, gynæcological, and obstetric specimens

For a short time he was on the surgical staff of the North West London Hospital and of the Cancer Hospital, later on he was for a time surgeon to the Poplar Hospital for Accidents He was appointed assistant surgeon to the Westminster Hospital in 1887, when he resigned his other posts He at once made his mark at Westminster, within ten years he became senior surgeon and lecturer on surgery, and was recognised by all his colleagues as a notable acquisition to the staff Meanwhile his wide knowledge of surgical pathology and his previous experience enabled him to restore and write a catalogue of, the hospital museum, and later he made use of this accurate and multifarious information and became the author of a manual of surgery in three volumes His appointments as examiner included that in anatomy on the English Conjoint Board and in surgery at the Apothecaries Society and in recent years he had been examiner in surgery at the University of Ireland

Stonham s commanding spare figure, striking face, and the force he threw into speech and movement impressed not only students but colleagues and patients, while he possessed the skill that his dramatic appearance promised He was perfectly ambidextrous his long thin hands were used most skilfully he was a very rapid operator, beginning and ending quickly, yet proceeding with all due care and caution at critical points The following are crucial instances supplied to us by one of his colleagues of his surgical skill in combination with anatomical knowledge

A man had a rapidly increasing aneurysm of the *second* part of the *left* subclavian artery At the first operation Stonham ligatured the arterial branches distal to the sac at the second operation he divided the clavicle and ligatured the *first* part of the artery The man was seen some years afterwards by the writer of this note and his vascular condition had meanwhile been stationary Later the patient died in the country but efforts to obtain a post mortem examination failed Again by a truly major operation he removed the upper extremity along with the breast of a woman for malignant disease She got up with the wound healed 10 days after the operation and was able to leave the hospital "

Whilst busily engaged as a hospital surgeon and with private practice he distinguished himself in other ways He was in early life an enthusiastic mountaineer, and as a member of the Alpine Club made some noteworthy climbs He displayed, perhaps, his most original talent as an observer of birds He filled his house with a beautiful and rare collection of birds and their eggs, and he published a large book entitled " Birds of the British Islands," notable for the guidance he gave to the artist in making the drawings, as well as for the bird lore included in the text

Stonham s death was a direct casualty of the war He commenced his military service as surgeon in the Middlesex Yeomanry At the outbreak of the South African War he organised and took out as surgeon in chief the Imperial Yeomanry Field Hospital, of which he afterwards published a full account A remarkable incident happened not long after landing He, with his field ambulance, arrived soon after De Wet had attacked and captured the Derby Militia. It devolved upon Stonham as the senior officer present to arrange matters with the Boer general and to transmit the first knowledge of the mishap to the British authorities He was mentioned in despatches, received the medal with four clasps, and was made a C M G On his return he continued his ambulance work and devoted an immense amount of time to the training of recruits and to the provision of equipment and horses for a mounted ambulance In spite of endless difficulties from lack of funds and support, his unit was able to take part in manœuvres, and at the beginning of the present war was found ready He could have taken it out to France with the first Expeditionary Force Unfortunately he had to undergo the severest trial to his patience, his trained men and horses had to be transferred to fill up deficiencies elsewhere, and he had to spend a winter in East Anglia, replacing what had been taken from him At last he was ordered to Egypt, where he became Inspector of Hospitals the testimony to his good work in that position has been many sided and warm He was promoted to be Colonel in the Army Medical Service Very soon, alas, his health failed He had suffered in recent years from emphysematous attacks when a short holiday in the south at this time of year would restore him But last winter tried him severely, in Egypt he was again attacked, at a time when he was weakened by dengue and dysentery Forced to take sick leave he went to Cannes but failed to recuperate there as in previous years He reached home very weak, attacks of breathlessness continued, and he died on Feb 1st His funeral with military honours took place on Feb 3rd at Golder s Green At the same time a service was held in the chapel at Westminster Hospital, where the memory of Stonham will long be kept green

Sir Bryan Donkin writes —

I send you a few words in memory of my old friend and colleague Colonel Stonham whose untimely death I greatly mourn His loss will be felt deeply by all those who knew him well and by the hospital he served so ably and earnestly during his 29 years on the surgical staff He and I were intimate friends from almost the beginning of our acquaintance in 1887 until his death and were active colleagues at Westminster Hospital for about 12 years Others will doubtless write in detail about his marked ability as a surgeon My own opinion of the high skill and conscientious care that he showed in all his work caused me to seek his assistance in most of the cases that came before me requiring the aid of surgical opinion or operation, and I have many vivid memories both of his prompt and untiring help in serious cases, as well of his abounding generosity and warm sympathy in dealing with his patients As a teacher of surgery he ranked very high, as many of his pupils can certainly testify His name must stand out long and prominently among the best surgeons who have ever worked and taught at Westminster Hospital Stonham was a man of determined character, scrupulously honest, self reliant, and fearless These qualities, with which his manner and strikingly attractive appearance thoroughly harmonised, tended to inspire the confidence so widely given him, both by friends and patients He could and did speak out when occasion arose If he felt he had been in error he freely owned it, and if he failed in any contention where he knew himself to be right he surpassed the vast majority of humans in his total lack of vindictiveness His death is a grave loss to his profession, his hospital and school and all his personal friends, in whom he inspired both affection and respect

JAMES STANLEY NEWTON BOYD, M B, B S LOND, F R C S ENG,

LIEUTENANT COLONEL, R A M C (T F) SENIOR SURGEON TO CHARING CROSS HOSPITAL, ETC

WE have already announced the death of James Stanley Newton Boyd, senior surgeon to Charing Cross Hospital, which occurred on Feb 1st after a short illness

Stanley Boyd was born in Shrewsbury May 18th, 1856, his parents being Major James Boyd, 86th Regiment, and Emma, daughter of Henry Newton of Shrewsbury His boyhood was spent at St Heliers in Jersey, where his parents resided, and he began his medical education at University College, London, in 1872. Here he had a distinguished academic career, and many of his contemporaries came later to occupy very high positions in the medical profession. We may instance Sir A Pearce Gould, Mr A J Pepper, Sir Victor Horsley, Mr C J Bond, and the late Colonel Stonham, whose death occurred on the same day, and whose obituary we publish this week He was house physician to Wilson Fox and house surgeon to John Marshall, and was, no doubt, much influenced by the latter's teaching, especially in the application of scientific investigation to the practice of surgery Boyd, like others of his date, owed much of his subsequent success to that disciple of Lister and Billroth, Marcus Beck, whose teaching of the science and the art of surgery was an outstanding feature of University College Hospital at that time He passed his examinations with honour to himself and his medical school, taking the gold medal in anatomy at the first M B at London University, and honours in his final M.B, B S in medicine and obstetrics in 1879 He became F.R C S Eng in 1881 After graduating he became demonstrator of anatomy and later of practical surgery in the medical school, and surgical registrar in the hospital The experience acquired in the last post had a great influence on his future career By conscientious devotion to the duties of this office he laid the foundation of his thorough knowledge of pathology and of its important bearings in surgical practice It enabled him to describe precisely the details of an operation and also of any subsequent microscopic investigation In later life he would often refer to the value which such an appointment is to a young surgeon if he takes full advantage of its opportunities.

In 1882 Boyd was appointed assistant surgeon to Charing Cross Hospital, and it was soon evident that he was an acquisition to the anatomical and surgical teaching of the hospital He became full surgeon in 1891, and since 1905 he had been sen surgeon to the hospital In the interval he h most of the important posts at the hospital and attached school He was lecturer on anatomy fr 1888 to 1897, pathologist from 1886 to 1888, dean the school from 1890 to 1895, lecturer on operati surgery from 1899 to 1901, and lecturer on surg from 1896 to 1905 His lectures both in anatom and surgery were remarkably thorough He w treasurer to the school in 1906, holding the p till 1911 during a most critical period of the school's history As chairman of the medical commit of the hospital and of the school committee, h showed much zeal and devotion in forwarding th interests, welfare, and progress of both, alw bearing in mind that the benefits were mutuall reciprocal Though not an athlete himself h was a great believer and supporter of athletics a means of improving the moral and character o a school of the University

Despite his responsible duties at the Char Cross Hospital Boyd found time to hold oth appointments with credit to himself and benefit t others At the time of his death he was surge to the Hospital for Consumption and Diseases o the Chest, Brompton, and consulting surgeon t Paddington Green Hospital for Children and to th New Hospital for Women, while he was also on th honorary staff of certain suburban hospitals Sin the beginning of the war, in addition to h multifarious hospital and arduous private wo he had been attending and operating daily at th 4th London General Hospital in his capacity o Lieutenant Colonel R A M C (T F) and a memb of the *à la suite* staff He was elected upon th Council of the Royal College of Surgeons of Engla in July, 1914, having previously been a member o the Court of Examiners He examined also in surgery at the University of Cambridge

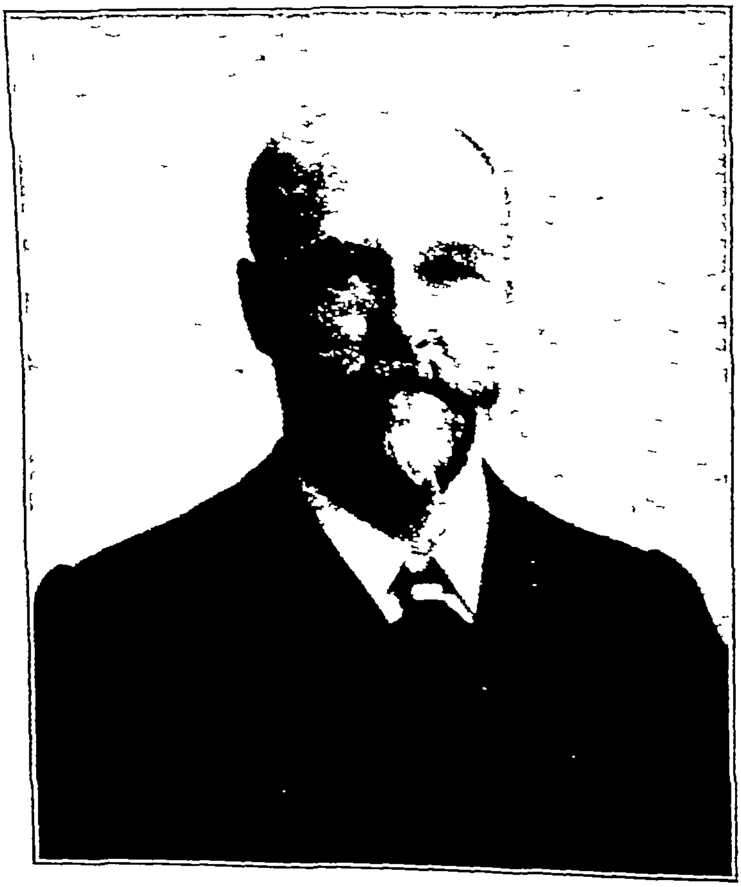
Stanley Boyd wrote no treatise on surgery bearing his name, although his wide pathological clinical, and practical knowledge would have justified him in such an undertaking But he was frequently asked to supervise the work o others, and in this way he was chosen to edit the twelfth edition of Druitt's "Vade Mecum" in 18 and also the seventh edition of the well known work "Pathology and Morbid Anatomy" of his old friend and colleague at Charing Cross Hospital Dr T H Green He also wrote articles in Heath's "*Dictionary of Surgery*" ("Hospital Mo tality and Hospitalism"), in Quain's "Dictionar of Medicine" ("Diseases of Mouth, Tongue, and Veins"), in Treves's "System of Surger ("Fractures"), in "*Encyclopædia Medica*, vol i ("Aneurysm"), and made many informing an lucid contributions to medical journals and to th proceedings of medical societies Amongst which may be named a paper read at the Royal Medical and Chirurgical Society in 1893 on "Artificial Anus treated by Resection and Enterorrhaphy b Maunsell's Method," and others on "Oöphorectomy in Cancer of the Breast," in 1897, and on "Can of the Tongue, Mouth, and Fauces," with W H Unwin, in *Practitioner* in 1903 He was moreove a brilliant operator, bold but always careful, and experienced in every branch of surgery He w keenly interested in the operative treatment o malignant disease, especially where the or mouth or fauces were involved and h success in radical operations for these conditions was in some measure due to his expert anatomical knowledge The best tribute to his skill m perhaps be estimated by the number o lleagues who owe him a deep debt of gratitude r his professional services either to themselves members of their family

Boyd was a man of very high principles Beneath rather reserved and, to some people, matter of ct manner there lay a very sincere warm hearted ture, ever ready to rejoice with his friends in eir success and to show active and generous mpathy in distress He hated all sham and pocrisy and had no use for slackers or slackness work, and this soon became appreciated by the udents, and when acting as dean he applied these nciples in the interest of the school.

Some of Boyd's professional and social connections were not always accepted at first but later ents have shown that he was a far seeing an. In the early days of the Women's School Medicine he as a lecturer n anatomy and uch of the uccess of that hool was due o him. He had he courage of is convictions nd never failed o advocate the laims of women o be admitted to he examinations f the Colleges nd Universities ike all pioneers n this movement he became npopular in ome quarters for time. On the ifficult subject f the proper evelopment of he University of ondon he had ery definite views He was among those who hold that the est way to reorganise the University of London as a eaching centre as far as medicine is concerned, would be to concentrate in a few centres the instruction in the preliminary sciences and much of the success which has now come to Charing Cross Hospital Medical School by its amalgamation for that purpose with King's College could have been effected years ago had the counsels of Stanley Boyd been adopted. Over 20 years ago he advocated in the public press that Charing Cross Hospital should be removed to a suburb south of the Thames This led to much opposition but his project has quite recently been adopted by a neighbouring hospital showing that the policy had at the time much to be said for it He was indeed a man with a broad outlook, and willing to work hard and to submit to much criticism for the sake of his fine ideals In 1893 he married Florence Nightingale Toms, M D, who became surgeon to the New Hospital for Women and subsequently held the post of lecturer on gynæcology at the Royal Free Hospital. At her death in 1910 she was senior surgeon at the New Hospital and was acknowledged to be a skilful surgeon and clinician. Stanley Boyd had a true helpmate in his wife, and her death made a great difference in his life His mother and one sister survive him

Dr Amand Routh writes —

Having entered University College Hospital as a student in 1873 the year following the entry of Stanley Boyd, and with similar sequence having joined the staff of Charing Cross Hospital in 1883 I have had almost daily opportunity of appreciating his personal integrity and professional uprightness and skill during over 40 years The late Montague Murray, F W Mott, and the late C J Arkle soon joined us as assistant physicians at Charing Cross Hospital, coming also from University College and we worked in perfect harmony Boyd laboured with disinterested zeal for the welfare of the students both during their hospital career and afterwards, and there was keen competition to become his house surgeon. His advice was sought and usually accepted by both colleagues and students, and his surgical opinion and help were similarly coveted in personal emergencies His friendship was deep and true, demonstrated mainly by acts of unselfishness and his sympathy was genuine, but not on the surface it was sometimes only realised when his help was being utilised in a crisis He never failed one in emergency and his counsel was so sound, so generous, and so clearly expressed that it always helped to clarify the outlook and lighten the difficulties of the situation.



JAMES STANLEY NEWTON BOYD

(Reproduced from a photograph by Ella Martin

As an instance of his unselfish impartiality I well remember how he acted when the obstetric physicians sought permission to perform all gynæcological operations upon their own cases Most of the major operations had hitherto been in the hands of the surgeons Boyd especially doing the bulk of the abdominal work. As soon as he realised that gynæcology was becoming a surgical specialty he helped to have all such surgical restrictions removed although he knew and so stated that the change would inevitably lead to the majority of major gynæcological operations going to the special rather than to the general wards The unexpected death of Stanley Boyd has startled and distressed his old friends more than any professional loss since the death of Montague Murray in 1907 Their characters and lives were very similar and their outlook on this world and the next was governed by a deep but unostentatious piety which controlled all their actions Such men as these exert an enormous influence upon the heart of a medical school, and their places will be difficult to adequately fill.

The War.

THE CASUALTY LIST

THE following medical officer appears among the casualties announced since our last issue —

Wounded

Lieutenant N A Scott, R A M C

DEATHS AMONG THE SONS OF MEDICAL MEN

The following sons of medical men must be added to our lists of those who have fallen during the war —

Second Lieutenant G D Murray, 12th Battalion Northumberland Fusiliers, son of the late Dr W D Murray, of Clapham Common, London, S W

Lieutenant J S Reed, 1st Buffs, attached to the Royal Flying Corps, only son of Dr J S Reed, of Gorleston, Suffolk

Lieutenant C W Turton, 6th Royal Sussex Regiment (T.F), younger son of Mr J Turton, F.R C S, of Brighton

THE EMPLOYMENT OF WOMEN IN MILITARY HOSPITALS

The replacement of male by female labour when this is physically possible has reached its logical conclusion in the new regulations issued for the employment of women in military hospitals These have been drawn up in consultation with the Joint Voluntary Aid Committee and concern two main classes of women —1 General service women 2 Labour staff, both of which will be engaged by the officer commanding, in the former case in coöperation with the county director Women living in their homes in the vicinity of the hospital will be given preference, but where sufficient of these are not available the Aid Committee will be asked to obtain offers from further afield

The Conditions of Employment as far as they Concern the First Class, the General Service Women

1 *Classification* —The following classes are marked out (*a*) Clerks on ordinary clerical work, including typists, telephonists, laboratory assistants (untrained) (including X ray attendants), storekeepers (*b*) Women with special technical qualifications requiring previous training, such as dispensers, head cooks, assistant cooks, trained laboratory assistants (*c*) Head clerks, including the head clerk appointed as the general service superintendent

2 *Rates of wages* —Remuneration for the various classes will be as follows (*a*) Inclusive weekly wages ranging from 20*s* to 26*s* (*b*) Dispensers will receive inclusive weekly wages ranging from 40*s* to 45*s* in the case of those possessing both the major and minor pharmaceutical certificates, from 28*s* to 30*s* in the case of those possessing only the Apothecaries Hall certificate Head cooks 20*s* to 25*s* a week plus meals if non resident, £30 to £40 a year plus meals if resident Assistant cooks 16*s* to 18*s* a week plus meals if non resident, £20 to £25 a year plus meals if resident A laboratory assistant (trained) an inclusive weekly wage of 25*s* to 30*s* (*c*) Head clerks will receive inclusive weekly wages ranging from 26*s* to 33*s* the general service superintendent 33*s* to 35*s*

The wages and wage limits stated above for all classes are intended to cover all time worked and are based on the understanding that no food or quarters are provided except where otherwise stated They will apply to all service whether probationary or no Dinner and tea will be provided where desirable at the hospital in which case a deduction of 5*s* a week will be made from the weekly wages of the women concerned

3 *Uniform* —General service women will be required after the completion of their probationary period to provide themselves with the regulation Voluntary Aid Detachment uniform. Towards this an allowance of £4 will be given on signing the agreement

4 *Probation and agreement* —General service women will be appointed on probation for one month. Their services, if not deemed satisfactory, may be dispensed with immediately at any time during the period of probation On the termination of the probationary period they will be required to sign an agreement for service for a period of 12 months or the duration of the war, whichever is less The form of agreement will include a clause empowering the officer commanding to terminate the agreement at any time on giving in general, one month's notice, and in the case of unsuitability or incompetence one week's notice.

5 *Travelling expenses* —In cases where a certificate is received from the Joint Voluntary Aid Committee that a woman has had to travel by rail on first joining the hospital, necessary travelling expenses, including third class rail fare will be refunded by the officer commanding

6 *Regulations* —All general service women employed in a hospital will be under the control of the officer commanding, and will be dealt with as regularly employed persons under the regulations for civilian subordinates, except where otherwise specially provided for General service women will be dealt with under the provisions of Section 47 of the National Health Insurance Act Medical attendance in cases of ordinary illness is normally provided by panel doctors but there is no objection to the provision of medical attendance for general service women by the hospital where the officer commanding considers this desirable

7 *Establishments* —Where general service women are employed a general service superintendent should be appointed, where one or more head clerks are employed one of them must be selected to act as general service superintendent at the same time Head clerks may be appointed where necessary, but not exceeding one (including the head clerk acting as general service superintendent) to five women clerks Head cooks may be appointed where it is found necessary to have a skilled woman in charge of the trained cooks but not more than one may be appointed to each kitchen

8 *Discipline* —The general service superintendent will under the control of the officer commanding, be responsible for the discipline and general welfare of the general service women, except those working inside the wards, who, while so employed will be under the supervision of the matron

9 *Women already engaged* —Women who have already been engaged under other terms may retain their rates and conditions where more favourable, but where the officer commanding considers it necessary to bring them under the new terms and conditions he may do so after giving reasonable notice

We have given these conditions of employment at length, as the service is one which will appeal with especial force to the wives sisters, and daughters of medical men and to other women who take a special interest in hospital work We understand that there are already over 2000 Voluntary Aid workers employed on general service, and that the demand for trained dispensers is at present greater than the supply

DISTINCTIVE UNIFORMS FOR MEDICAL OFFICERS —A Swiss correspondent writes ' The large number of doctors of all nationalities figuring among the killed and wounded has formed the subject of a special investigation by Professor Combe the Lausanne surgeon Dr Combe discussed the question with French and German military doctors alike and on the information thus acquired has formed the conclusion that the high percentage of such losses is due to the fact that in all the armies the uniforms of medical men resemble those of the combatants, and that it is impossible to discern any difference between them from a distance In his report which is now being considered by Swiss medical associations Dr Combe proposes in agreement with many eminent French German and Austrian doctors that doctors belonging to all the armies should wear similar uniforms extremely vivid and visible in character

Dr Harrington Sainsbury writes —

As one of Stanley Boyd's oldest friends, may I be allowed a little space in which to attempt a brief record of the man as I knew him? Our friendship began over 40 years ago at University College, London (he had come up to London from Jersey in 1872), it continued without a break and in close association until his death Marcus Aurelius devotes the first chapter of his 'Thoughts" to the several personalities which came into his life, and he ends up "To the gods I am indebted for having good grandfathers, good parents a good sister, good teachers, good associates, good kinsmen and friends, nearly everything good" Boyd's debt to the heavenly powers was a like one I can go back to the charm of his Jersey home at St. Heliers, and recall happy memories of a visit there when the circle was still complete, Major and Mrs Boyd, a younger sister and brother forming that circle, and I can see there, in the simplicities and integrities and unaffected enjoyment of life which prevailed, the natural source of the qualities which characterised and adorned him It was a military home where duty figured largely and cheerfully, and it has always seemed to me that in consequence Boyd retained much of the soldier's outlook all through his life this impression has been deepened since the war began. When Boyd came to London he saw a great deal of his uncle, Henry Newton, who had by then retired from a judgeship in the Indian Courts after a distinguished career in that country Mr Newton, who regarded him almost as a son had a great influence over him, and to that influence on the spiritual side of things much may be traced, in particular his sympathies with the Society of Friends A great friend of his at University College was William S Tuke, the prognostics of whose life were brilliant, but the 'dark economy of heaven" did not see fit to fulfil them here Through him Boyd came to know Dr Hack Tuke and his family, of long established Quaker origin and traditions, here he found kindred sympathetic influences and friendships which endured Among his contemporaries at University College, with whom he was associated, whom he influenced, and by whom in turn he was influenced, I would name in particular Victor Horsley, C J Bond of Leicester, Dawson Williams, Arthur Quarry Silcock, Amand Routh, F W Mott, Montague Murray, the last three became colleagues of his at Charing Cross Hospital Amongst his teachers at University College Hospital one name stands out pre eminently, that of Marcus Beck, a man who figured chiefly in his influence upon others and in the affectionate remembrance which he implanted

From about 1880 onwards began his connexion with the London School of Medicine for Women, to which in the chivalrous way which was his wont, he gave without stint time and labour, here, as always, recognising one standard only for himself as for others—namely, the highest Many friendships had their origin in this school, and here he found, as his great reward, his wife, Florence Nightingale Toms They were married in 1889 and with his marriage began the happiest and fullest period of his life, for the two were united not only by the bonds of affection, but by an exceptional community of tastes, interests, and ideals, they were husband and wife and at the same time true comrades Mrs Boyd died in 1910, to the sorrow of all who knew her to his grief before all Henceforward he continued to work with the same thoroughness but not with the same incentive, for joys could no longer be doubled, sorrows halved He left special directions that his funeral should follow as far as possible, in all details, the funeral service of his wife, and if this was departed from by the introduction of a military element it was done so after full consideration and in the belief that Mrs Stanley Boyd would have welcomed the departure, proud of the work which he had given to his country in its hour of need His mother and sister, who have lived with him since his wife's death, may well be proud of him and herein find their truest consolation

FRANCIS GETHIN HOPKINS M D B CH DUB,

LIEUTENANT R A M C LATE PRINCIPAL MEDICAL OFFICER, GOLD COAST COLONY
